SATURDAY, JANUARY 9, 1937

## MORTALITY FROM HEART DISEASE

Almost all recent statistics on the mortality from heart disease indicate a rapid rise in deaths from this cause. Is this increase real or apparent? Several factors enter into the gross figures. The rise in the average age of the population is an obvious one. The method of reporting heart disease on death certificates also affects the gross figures. The true interpretation, therefore, resolves itself into an analysis of the elements affecting mortality from heart disease into their various components. With this in view, Hedley<sup>1</sup> has reported a series of studies on the mortality from heart disease.

There is a difference, he points out, between the methods of clinical recording of heart disease and the mortality records as obtained from death certificates. The salient feature in modern clinical diagnosis and classification is the grouping of diseases and disorders of the heart on an etiologic basis. Thus, one of the chief difficulties in attempting to describe cardiac disease on any other basis than that of etiology is that dissimilar conditions are thereby placed in the same category. The clinical, pathologic and epidemiologic pictures differ with the causative factors. Quite different is the method of recording heart disease according to the International List of Causes of Death. This guide came into use during a period when interest centered around the discovery and interpretation of organic lesions rather than etiology. Although changes have been made since that time, the main basis of classification still rests on an anatomic interpretation. In addition to this obsolescence of terminology, the list fails to recognize many deaths due to heart disease. Thus, for example, deaths from rheumatic carditis are frequently placed under the title "rheumatic fever." Similarly, deaths from Sydenham's chorea are placed under "other diseases of the nervous system," the inference being that the patient dies of cerebral manifestations. Another factor that definitely affects the recording of deaths is the Manual of Joint Causes of

Death. It is used to determine which of two or more conditions listed on a death certificate takes precedence as the cause of death. For instance, if heart disease and nephritis are both mentioned on a death certificate, the cause of death is listed as nephritis. Heart disease is considered secondary to almost all the other known factors. Causative cardiac conditions and associated circulatory disorders are consequently lost when reported. The present system of recording death would seem no longer in accordance with modern clinical conceptions of heart disease. Failure to consider certain etiologic factors makes it impossible to evaluate their significance in causing heart disease.

Another important element in the classification of deaths from heart disease is pointed out by Hedley. In the last analysis, any statistical studies of mortality must be based on the individual death certificates. The ultimate responsibility for the accuracy of any scheme of tabulation is therefore dependent on the integrity, interest and training of those furnishing the designated authorities with the required information. Some of the accepted cardiac diagnoses serve, however, only as a satisfactory screen behind which to hide a diagnostic uncertainty. The ultimate importance of the death certificate should thus be realized by the physicians who fill them out, and every effort should be made to have them convey a correct interpretation of the facts. Even when this is done, however, the method of ascribing precedence to one cause of death over another previously referred to and controlled by the Manual of Joint Causes of Death may seriously affect the ultimate figures. Thus, in some statistics cited by Hedley, coronary thrombosis was diagnosed 144 times as a primary cause of death and 115 times as a contributory factor, appearing on 259 death certificates. In the official tabulation of causes of death, however, the cause was ascribed to disease of the coronary arteries in only seventy-eight instances, owing to the system of relative weighting of the significance of various conditions as causes of death.

As a result of a study of the hospital records of deaths certified under heart disease in the Washington, D. C., hospitals during 1932, Hedley felt that he could conclude that the accuracy with which the mortality from heart disease is reported and recorded leaves much to be desired. Some of the errors could be attributed to laxity or misdiagnoses on the part of the reporting physician, while others were due to the manner of assorting and tabulating mortality statistics. The chief source of error on the part of those signing death certificates could be ascribed to too great tendencies to certify as heart disease other conditions characterized by terminal congestive heart failure. Among 355 deaths officially recorded as being due to heart disease, which occurred in hospitals, seventy-one, or approximately 20 per cent, were from known noncardiac causes. Many deaths from heart disease are not officially recorded as such. Many conditions other than heart disease and most of the etiologic factors responsible

field at full aperture. A slower lens, such as  $f/4.5$ , is entirely adequate, since it is usually used at an aperture of from  $f/8$  to  $f/32$  in order to provide sufficient depth of field to insure the entire area of interest being sharply in focus.<sup>2</sup>

**Shutters.**—Since high-speed work is rarely necessary in clinical photography, focal plane shutters offer no distinct advantages. As has been previously mentioned, speeds of one-tenth, one-fifth, one-half and one second are often required; therefore diaphragm or "between-the-lens" shutters, such as Compur, Ilex, Wollensak and Optimo shutters, are preferable.

#### ACCESSORY EQUIPMENT

A tripod, preferably with a tilting top, on which to set the camera is a very useful accessory. A folding metal tripod is portable and may be purchased inexpensively. A good addition to a tripod, if the tripod has no tilting top and the camera is not too heavy, is an Eastman Optipod, a ball-and-socket swivel arrangement, which may be attached to the tripod and allows the tilting of the camera in any direction. A lens shade will prove itself a boon in preventing glare from the reflections of light on the ceiling, walls and floor. Necessary equipment for developing and printing film and paper is discussed under the heading "Photographic Processes," and essential illuminants are outlined under "The Photography of the Patient by Visible Light."

Optional equipment includes filters for contrast and color correction, such as Wratten A, B, C, K<sub>2</sub>, G, X<sub>1</sub> and X<sub>2</sub> filters, an enlarger or device to convert one's camera into an enlarger, a source of light for photomicrography, an exposure meter, and special apparatus for gastric, ophthalmoscopic, rectal and cystoscopic photography.

#### PHOTOGRAPHIC PROCESSES

**The Darkroom.**—While developing and printing may be relegated to a reliable photofinisher, most physicians will probably get better results by processing their own films. A photographic darkroom is, of course, a necessity. If one does not possess an x-ray darkroom, a closet or small empty room may easily be converted into a darkroom by adding a sink and a few tables and shelves. The windows must be made lightproof unless work is to be confined to nighttime. A small electric fan will help ventilation considerably. The ordinary x-ray safelight will be unsuitable for most of the negative materials used and therefore it will be necessary to procure one or more safelights according to the type of materials handled. A dark red safelight, such as a Wratten Series 2 Safelight, will be found a convenience in working with orthochromatic materials, and, if a light must be used in developing panchromatic emulsions, a deep green light, such as the Wratten Series 3 Safelight, is recommended. An orange electric safelight or Wratten Series O Safelight is a necessity for use with bromide papers, developing-out papers and lantern slides.

**Developing.**—Films and plates may be developed by the tray or tank method. For tray development three glass, enameled or hard rubber trays for the developing solution, acid short-stop, and fixing reagent are required. Tank development is much preferred because of the more even development and lessened handling of the film. For packs or cut films rectangular hard-rubber tanks are most suitable, and for roll films

cylindric or rectangular tanks may be used. Tray development will give excellent results provided development is carried out in the dark or with the proper safelight. A clock that ticks off quarter or half seconds is a convenience in timing development of paper or film, and a thermometer will be found necessary to measure the temperature of solutions.

There is a wide latitude in the choice of developing solutions. Development for eight minutes in ordinary x-ray developer will yield fairly good negatives. Developer is conveniently dispensed in small glass tubes known as M. Q. tubes, which may be used not only for developing films and plates but also for bromide and developing-out papers. Eastman Film and Plate Developer in tube form and Eastman Universal Developer are both excellent formulas. If one wishes to be scientifically exact, the best formulas are those recommended by the manufacturer for a particular emulsion used. For a small investment one may procure a set of scales and all necessary chemicals to compound formulas.

A good all-round developer for films and plates is the Eastman D-61a formula.<sup>3</sup> A developer yielding fairly strong contrast in supersensitive panchromatic emulsions and Panatomic film is D-72, which may be compounded<sup>3</sup> or purchased from photographic supply houses ready to mix with water to give 1 quart, 2 quarts or 1 gallon of solution.

Fine grain developers will be necessary for miniature films or other fine grain films whenever great enlargements are contemplated. Since fine grain is dependent mostly on the character of the emulsion and only to a limited extent on the developer, it is essential to use a fine grain emulsion. Full exposure, slight underdevelopment employing a slow acting developer to minimize the clumping of silver particles, and rapid drying of the film will insure the best results. There are many fine grain developers on the market, among which the D-76 developer<sup>3</sup> is very popular. This developer may be compounded or obtained ready to mix with water and will give splendid results in most cases. Some ultra fine grain developers contain paraphenylenediamine, a powerful poison, and require approximately double exposures and development. The Eastman Kodak Company has recently marketed an ultra fine grain developer which is nonpoisonous and faster acting than paraphenylenediamine.<sup>4</sup>

**Fixing.**—The use of an intermediate acetic acid bath helps prevent staining and prolongs the life of the fixing bath. The following bath should be made up fresh: water, 32 ounces; acetic acid 28 per cent, 1½ ounces.

The negative is next transferred to an acid-hypo fixing solution at 65 F. and allowed to remain approximately twenty minutes, or ten minutes longer than it takes for the white color of the emulsion to disappear. The fixing bath need not be prepared fresh and may be used over and over again until the action slows up and more than from five to seven minutes is necessary for the negative to clear. White light may be turned on in the darkroom after the film has been in the fixing solution for approximately two minutes. Acid hypo may be purchased as a prepared powder to make up the fixing solution, or the solution may be compounded from formula.<sup>3</sup>

3. Eastman processing formulas are published in the booklet "Eastman Professional Films," which may be obtained on application to the Eastman Kodak Company, Rochester, N. Y.

4. Vittum, P. W., and Crabtree, J. I.: A New Fine Grain Developer. Camera Craft 42: 587-597 (Dec.), 1935.

2. The Eastman Clinical Camera is fitted with an  $f/7.7$  anastigmatic lens.

ease load than to put on special workers, except that specially trained persons may be necessary and valuable in a supervisory and consultant capacity.

5. The section on cooperation of the private physician in the control of venereal diseases made a report which indicated the dual responsibility of the physician in any case of communicable disease, including the venereal diseases. This responsibility is for the patient and for the community. The section recommended that the responsibilities of public health officials include provision of easy, convenient and postage-free forms for necessary reporting, omitting names or other too positive identification where circumstances indicate, and providing most careful safeguards for confidential and secret keeping of the records; the distribution, gratis where required, of necessary drugs for the treatment of the venereal diseases; the provision, gratis, of necessary laboratory services, including serologic tests, dark-field examinations and the examination of pus for the gonococcus; hospitalization at public expense where necessary, especially for the syphilitic pregnant woman; and provision of consultation service to physicians, and to clinics apart from teaching centers, wherever practical.

The principles here presented seemed in general to meet with the approval of all groups represented. Recognition was given to the fact that conditions in the United States differ widely in different localities and even sometimes within a single community and that programs, subject only to general fundamentals, must be varied and adapted to meet local needs. Recognition was given in all the sections to the necessity for carrying out the program in the states and local communities through cooperation from the beginning between state health departments and state medical societies, and between local health departments and local medical societies.

In all probability most indigent patients in denser population centers will need to be treated in clinics. In smaller communities and rural areas, treatment of the indigent was recommended through the offices of family physicians. The recommendations included payment of the physician on such a basis as might locally be agreed on for services rendered to indigent patients. Certain questions were raised relating to the lack of uniformity of instruction in syphilology in the medical schools. The question was debated in the section on medical cooperation under the heading of undergraduate education and a resolution was adopted requesting the Surgeon General to refer the matter of undergraduate education in syphilology to the Council on Medical Education and Hospitals of the American Medical Association, and to the Association of American Medical Colleges. Stress was laid particularly on the desirability of carrying postgraduate educational efforts as well as the machinery of cooperation through the channels of organized medicine in the state and the local community.

## Current Comment

### AMERICAN MEDICAL ASSOCIATION BULLETIN SECTION

Last week THE JOURNAL published the first issue of the new Bulletin Section, which is to record the economic, social and business aspects of medical practice as well as the affairs of the Association. Certain changes are now made in this department to meet post office regulations. In the current issue, it appears following the Current Medical Literature department, just preceding the second advertising section, and the pages as numbered carry an additional letter B, indicating that they are paged for the *Bulletin*.

### WHAT'S IN A NAME?

The emphasis placed on prompt and accurate registration of birth certification is amply borne out by the facts of its importance. Thus one example of many is brought out in a recent press bulletin from the Maryland Department of Health.<sup>1</sup> A young American, now a resident of Poland, is experiencing some difficulty in returning to Maryland, his native state. The physician in attendance at his birth twenty years ago wrote "female" instead of "male" on the birth certificate recorded in the state bureau of vital statistics. When the young man was about 7 years old, the father took the family to Poland. His mother, whose health was not good, and the two sons remained in Poland when the father returned to Maryland. A difficulty resulting from the error on the birth certificate remaining undetected for so long a period seems like a relatively inconsequential matter. Nevertheless, it is taking the combined efforts of the bureau of vital statistics, the young man's family, the family physician and the priest of the church in which he was baptized to bring about a satisfactory correction of this minor mistake. Further emphasis is accorded this point in a weekly health message from the United States Public Health Service and the Iowa State Department of Health.<sup>2</sup> This states, in part: "With the passing of the Old Age Assistance Act in the state of Iowa, many citizens have been called on to produce their birth certificate to prove identity and nativity. In many cases the applicant for a birth certificate has run into difficulty because of the death of parents, friends or perhaps the physician who was in attendance at the birth." Such registration is, in fact, at times essential and at others of great importance. It establishes the name, the date of birth and the child's parentage. The birth certificate may be required for permission to enter school, to work, to hold office or vote, or to establish age in connection with granting of pensions or inheritance of property. Both bulletins advise prompt choice of the child's name with the prompt and accurate filing without use of nicknames or anything else that might at a later date cause some question as to the accuracy of the certificate.

1. Department of Health, State of Maryland, Press Bull. 641, Nov. 5, 1936.

2. U. S. Pub. Health Service and Iowa State Department of Health, Health Message 526, Nov. 9, 1936.

recommended by the manufacturers of the paper used may be employed. The washing, drying and squeegeeing on polished ferrotype tins are carried out in the manner described for contact prints.

Almost any glossy bromide paper may be used, and varying grades of contrast—soft, normal or contrast—will tend to compensate for variations in negative quality. For reproduction purposes a sharp contrasty enlargement is best.

While enlargements of 4 or 5 diameters may be made in most sharp negatives without objectional grain, greater enlargements will necessitate the use of a fine grain negative developed in a fine grain developer such as D-76.

*Making Lantern Slides.*—Negatives to be used for the purpose of making lantern slides must be as nearly perfect as possible, because tiny defects, such as blurred images, scratches and pinholes, are tremendously magnified during the process of projection.

Lantern slides are really positive transparencies, and the technic of making slides is as simple as making contact prints or enlargements except that glass plates are used instead of paper. Developing, fixing, washing and drying are carried out in the same manner as for ordinary negative plates.

In making a lantern slide by contact printing, a regular printing frame is used and the emulsion side of the slide is placed in contact with the emulsion side of the negative. Exposure depends on the density of the negative and the strength of the light source. For Eastman Regular Lantern Slide Plates, which are recommended for normal negatives, at a distance of 6 feet from a 25 watt frosted lamp, the exposure is approximately five seconds. For the Eastman Slow Lantern Slide Plates, recommended for soft negatives, the exposure is approximately fifteen seconds. The chief disadvantage of contact printing is that negatives larger than the slide can be only partly included.

Projection printing allows enlargement or reduction of the original negative, the method being exactly the same as for bromide paper. In making reductions, the bellows extension must be increased and the easel brought closer to the lens. Three or four stout drawing pins attached to the easel will serve as a support for the plate during exposure. Focusing must be needle sharp, and preliminary focusing may be carried out on a spoiled undeveloped slide.

Full development should be secured with the use of a standard metol hydroquinone developer. Rinsing, fixing and drying follow, and subsequent reduction or intensification may be carried out if necessary. An orange safelight similar to the safelight for bromide paper may be used during the exposure and processing of the slides.

Varnishing the slide with Eastman Lantern Slide Varnish will protect it against "dewing." A mask of black paper with an opening 3 inches by  $2\frac{1}{4}$  inches should next be applied, or undesired portions of the slide may be excluded by means of Eastman Lantern Slide Binders applied to the emulsion side of the slide. The slide is then carefully dusted and bound to a cover-glass with gummed strips.

#### THE PHOTOGRAPHY OF THE PATIENT BY VISIBLE LIGHT

*The Background.*—In making a full length picture of a patient, or in photographing a part of the body, the background should be as inconspicuous as possible, in

order to avoid detracting interest from the principal subject. A medium gray background is the most practical and an ordinary gray hospital blanket will prove ideal for this purpose. Where much photography is to be done it may pay to construct a background by stretching gray cloth over a wooden frame 6 feet square. A useful portable background is an ordinary roller shade, one side of which is white, the other side gray or black. The background should contrast with the tone of the subject, and for a person of dark complexion or a colored person it may be advisable to utilize a white background in the form of a white blanket or sheet. In clinics or in places where a proper background cannot be obtained, the patient may be photographed against a plain wall. Best results are obtained with the subject several yards from the background. It is important to remember, in photographing patients in surroundings where the background is apt to prove distracting, that utilizing a wide opening of the lens will shorten the depth of field and may automatically throw the background out of focus. In photographing a part of the body such as an arm or a leg, the part may be conveniently rested on the examining table over which there has been stretched a blanket or sheet.

*Illumination.*—While photographs may be made outdoors in direct sunlight or shade, the majority of pictures must of necessity be taken indoors, where the illumination is relatively poor. Artificial sources of light are consequently essential, and there are available two types of illuminants: Photoflood bulbs and Photoflash lamps.

The Photoflood bulb is a 65 volt Mazda lamp, which, when burned on a 115 volt circuit, produces the light equivalent of a 750 watt lamp. Each bulb consumes 2.15 amperes, and as many as five bulbs may be used safely on an ordinary house-lighting circuit. Although the life of the bulb is rated at two hours, the general experience is that Photoflood bulbs burn considerably longer. Photoflood bulbs are economical sources of light and are sufficiently small to be portable. The efficiency of the bulb is considerably increased by a reflector. Ordinary metal shades are satisfactory, but conical metal reflectors are preferable. Kodaflectors or other Photoflood reflectors are very convenient and may be purchased at small expense. The number of lamps used depends of course on the extent of the area to be photographed. One bulb will be sufficient for small lesions, but large areas will require as many as four or five Photofloods. Two lamps with two bulbs mounted in each will suffice for most purposes. The intense brilliance of the lights may be annoying to some patients and a diffusing screen made of several layers of muslin or cheese cloth will reduce the glare and produce a more even distribution of light. Unlike portraiture, the object is to reproduce detail accurately and to bring out deformities and blemishes rather than to soften them.

Flat lighting, in which the illumination is spread evenly over the subject minimizing shadows, is best suited for most subjects. This lighting may be obtained by arranging two lamps of equal intensity equidistant on each side of the subject. Three-quarter front lighting should be used where the face is to be photographed as for facial expression. The first lamp is placed 45 degrees above and to one side of the subject half way between the camera and the subject. The second lamp, focused on the shadow side of the face, is placed behind

## IOWA

**Personal.**—Dr. Albert E. Shaw has been elected coroner of Polk County to succeed William A. Carpenter; both are of Des Moines.—Dr. Milford E. Barnes, Iowa City, has been elected president of the Iowa Tuberculosis Association to fill the unexpired term of the late Dr. James A. Edwards, Oakdale.—Dr. Harry A. Stribley has been appointed in charge of a new clinic for the treatment of venereal disease which opened in Dubuque December 1.

**First District Health Unit.**—The first public health district in Iowa has been organized with Dr. William M. Trotter, formerly of Maxwell, as director. To be known as district number 1, the unit comprises the counties of Lyon, Osceola, Sioux, Plymouth, O'Brien and Cherokee. It will supplement but in no way interfere with health work now being carried out in the counties. Similar health districts are to be formed in other parts of the state as rapidly as trained personnel is available, it was reported.

**Society News.**—Dr. Karl A. Menninger, Topeka, Kan., will address the Linn County Medical Society, January 15, in Cedar Rapids. His subject will be "Various Forms of Self Destruction." Dr. John Royal Moore, Philadelphia, discussed "Fractures of the Neck of the Femur" before the society, December 17. Dr. Raymond J. Stephen, Cedar Rapids, read a paper on "The Ophthalmoscope in General Practice."—Dr. Percival Bailey, Chicago, discussed the treatment of common neurologic disorders before the Black Hawk County Medical Society in Waterloo, November 17.—At a meeting of the Marshall County Medical Society in Marshalltown, December 1, Dr. George B. Eusterman, Rochester, Minn., spoke on diagnosis and treatment of gastro-intestinal disorders.

## KENTUCKY

**Personal.**—Dr. Benjamin T. Black, Campbellsville, recently celebrated the fiftieth anniversary of his settling in that town. Dr. Black was graduated from the University of Louisville School of Medicine in 1885.

## LOUISIANA

**Health at New Orleans.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended December 26, indicate that the highest mortality rate (20.3) appears for New Orleans and that the rate for the group of cities as a whole was 11.9. The mortality rate for New Orleans for the corresponding period last year was 22.3 and for the group of cities as a whole 12.6. The annual rate for eighty-six cities for the fifty-two weeks of 1936 was 12 as against a rate of 11.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

## MAINE

**Society News.**—At a meeting of the Kennebec County Medical Association in Gardiner, November 19, the speakers included Drs. Merrill E. Joss, Richmond, on pregnancy with poliomyelitis, and Silas O. Clason, Gardiner, use of solution of posterior pituitary in labor.—Dr. Richard P. Jones, Belfast, read a paper before the Waldo County Medical Society in Belfast, November 19, entitled "A Review of Some of the More Common Blood Dyscrasias."—The Washington County Medical Society was addressed in Whiting, November 4, by Drs. Frederick T. Hill, Waterville, on "Bronchoscopy as an Aid to Diagnosis," and John O. Piper, Waterville, "Complications of Diabetes."—Dr. Robert H. Aldrich, Boston, addressed the York County Medical Society, recently, on "Gentian Violet and Aniline Dye Treatment of Burns."

## MARYLAND

**Dr. Rowland Honored.**—Special ceremonies were held at the University of Maryland School of Medicine, Baltimore, December 18, to commemorate the twentieth anniversary of Dr. James M. H. Rowland as dean. The occasion was also a part of the Founder's Day celebration. The speaker at the morning ceremony in honor of Dr. Rowland was Dr. Thurman D. Kitchin, president of Wake Forest College, Wake Forest, N. C. An oil portrait by Thomas C. Corner was presented

to the university by Dr. Charles Bagley Jr., acting for the faculty of the medical school. Dr. Walter D. Wise, professor of clinical surgery at the university, officiated as toastmaster at the banquet in the evening, and speakers included Drs. Alan M. Chesney, dean, Johns Hopkins University School of Medicine; Maurice C. Pincoffs, professor of medicine at Maryland, and Charles Reid Edwards, professor of clinical surgery at Maryland. Samuel K. Dennis, chief justice of the supreme court, Baltimore, also spoke. A bronze bust of Dr. Rowland made by his daughter, Mrs. Carl Clarke, was presented to the university by members of the family. Dr. Rowland is also professor of obstetrics.

## MASSACHUSETTS

**Personal.**—Dr. Frank H. Lahey, Boston, addressed the annual meeting of the local chapter of Alpha Omega Alpha Honorary Medical Fraternity in New Orleans, December 18, on "The Management of Biliary Tract Diseases." The meeting was open to the public.—Augustus Herman Gill, Ph.D., Belmont, professor emeritus of chemistry, Massachusetts Institute of Technology, and a member of the state board of health, died at his home, November 11, aged 72 years.

**Public Sunday Afternoon Lectures.**—A course of free public lectures will open at the Harvard University Medical School, Boston, January 10, to continue each Sunday afternoon until March 21. The following program will be presented:

Philip Drinker, Ch.E., Air Conditioning and Health, January 10.  
Dr. Soma Weiss, Blood Pressure—Low and High, January 17.  
Dr. Tracy J. Putnam, Pain and Its Treatment, January 24.  
Dr. Charles Macfie Campbell, Social Stress and Mental Health, January 31.  
Dr. William T. Salter, Cancer, February 7.  
Dr. Edward D. Churchill, Surgical Aid in Lung Diseases, February 14.  
Dr. Theodore L. Terry, The Care of the Eyes, February 21.  
Dr. Louis K. Diamond, The Anemic Child, February 28.  
Dr. William H. Robey, Preparing for a Comfortable Old Age, March 7.  
Dr. Arthur T. Hertig, Abnormal Terminations of Early Pregnancy, March 14.  
Dr. Joseph C. Aub, Glands of Internal Secretion and Human Activity, March 21.

## MICHIGAN

**Dr. Waggoner Named Professor of Psychiatry.**—Dr. Raymond W. Waggoner, associate professor of neurology, University of Michigan Medical School, Ann Arbor, has been appointed professor and director of the department of psychiatry. His appointment as director of the state psychopathic hospital was recently announced. In both positions Dr. Waggoner succeeds Dr. Albert M. Barrett, who died April 2, 1936. An alumnus of the school, he has been associated with its faculty since 1929.

**Society News.**—At a meeting of the Detroit Society of Neurology in Northville, November 19, the speakers included Thorlief G. Hegge, Ph.D., on "Psychological Variations in High Grade and Borderline Defectives."—Dr. Robert L. Schaefer, Detroit, addressed the Bay County Medical Society, November 11, on "Clinical Indications for the Anterior Pituitary-like Sex Hormone."—Dr. Martin H. Hoffmann, Eloise, discussed "Problems of Nervous Patients" before the Genesee County Medical Society, December 2.

**Memorial to Dr. Huber.**—The *Journal of Comparative Neurology* for December was designated the Huber Memorial Volume in honor of the late Dr. Gotthelf Carl Huber, who at the time of his death, Dec. 26, 1934, was dean of the University of Michigan Medical School, Ann Arbor. The issue contains primarily papers dealing with neuro-anatomic research done by the authors while working under Dr. Huber's direction. Dr. Huber graduated from the university when it was known as the University of Michigan Department of Medicine and Surgery in 1887. Identified with the school for many years in various capacities, he had been professor of anatomy and director of the anatomic laboratories since 1914 and dean since 1927.

**The Wayne County Programs.**—Dr. Logan Clendenen, Kansas City, Mo., addressed the Wayne County Medical Society, Detroit, January 4, on "Laryngological Causes of the Great War." Dr. Alice Hamilton, Boston, consultant, U. S. Department of Labor, will address the medical section, January 11, on "New Developments in the Field of Common Industrial Poisons." Dr. James B. Collip, professor of biochemistry, McGill University, Montreal, will discuss "Studies on the Anterior Pituitaries and Related Glands" before a general meeting, January 18, and Dr. Malcolm T. MacEachern of the American College of Surgeons, Chicago, "Trends in Medical Practice" before a meeting of the surgical section, January 25.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

### HOGAN SUPER-BREVATHERM SHORT WAVE DIATHERMY UNIT, MODEL 8901, ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, Chicago.

This unit is recommended for medical and surgical diathermy and for the application of therapeutic fever. It is essentially the same as the Hogan Super-Brevatherm Short Wave Diathermy Unit, Model 8898, which has been accepted by the Council.<sup>1</sup>

There has been no change in the circuit except for the inclusion of blocking condensers and such necessary wiring as found desirable for the operation of a cable electrode.

The apparatus is mounted in a wooden cabinet with a removable cabinet door, and all component parts are accessible for inspection and repairs. The circuit is of the well known tuned plate, tuned grid circuit, two tube push-pull oscillator. Two oscillator and two rectifying tubes are employed. All parts carrying short wave currents are mounted on either ceramic or other low-loss insulating materials. The patient's circuit for the inductance cable is capacitatively coupled, while the patient's circuit for the pad and cuff electrodes and surgical diathermy is inductively coupled to the oscillator. The inductively coupled patient's circuit is tuned to electrical resonance by means of a variable condenser. For regulation of the power input, primary winding of the plate current transformer is equipped with taps to vary the input current. A thermocouple ammeter is used to indicate electrical resonance. The interior of the cabinet is cooled by a forced draft motor driven fan.

Hogan Super-Brevatherm, Model 8901.

The power input, under maximum load, is about 1,100 watts. The wavelength is approximately 21 meters. Since there is no acceptable method of measuring the output power of short wave machines, this value is not given. The shipping weight of the unit is 137 pounds.

The power input, under maximum load, is about 1,100 watts. The wavelength is approximately 21 meters. Since there is no acceptable method of measuring the output power of short wave machines, this value is not given. The shipping weight of the unit is 137 pounds.

Schematic diagram of circuit.

In accordance with the regular procedure of considering devices submitted to the Council, the firm was asked to present evidence to substantiate the claims made in advertising matter and descriptive literature. The evidence presented by the firm designed to substantiate efficacy in heating human tissues was obtained as follows: The thighs of two vigorous men,

aged 29 and 31, weighing 158 and 185 pounds (72 and 83 Kg.) respectively, were used for the experiments. Three observations were made on each subject—two on the left leg and one on the right of each individual. Hypodermic thermocouples manufactured by Leeds and Northrup Company and a portable precision potentiometer manufactured by the same company were employed in the investigation. The potentiometer and the thermocouples were checked against a Bureau of Standards Thermometer and the readings were accurate to within 0.1 degree C. The skin temperatures under the electrodes and the subcutaneous, the oral and the deep muscle temperatures were observed. Hypodermic needle thermometers were inserted in the thigh to a depth of from 1½ to 2 inches, depending on their thicknesses, while the other needle was inserted subcutaneously beneath the skin structure. The maximum current intensity was regulated by the skin comfort or tolerance of the patient. A reading was taken both before and after a twenty minute application of the current. After each test the thigh was permitted to cool to normal temperature. The highest temperature attained was recorded as the final temperature in each instance.

Cuff electrodes used were of the standard type furnished with the apparatus; that is, sheet metal covered with felt. They were about 2 inches wide, one-half inch thick and 24 inches long. These electrodes were placed on top of the flannel wrapping, about 8 inches apart, in most cases encircling the entire thigh. In those cases in which they did not reach

TABLE 1.—Averages of Six Observations with Cuff Application

Oral Temperature F.		Subcutaneous Temperature F.		Deep Muscle Temperature F.	
Initial	Final	Initial	Final	Initial	Final
99.11	99.09	89.08	95.25	97.38	102.96

TABLE 2.—Averages of Six Observations with Coil Technic

Oral Temperature F.		Subcutaneous Temperature F.		Deep Muscle Temperature F.	
Initial	Final	Initial	Final	Initial	Final
98.95	99.03	89.95	98.61	98.11	105.75

around the thigh, the "open space" between the ends of the electrode was always at the posterior aspect of the thigh. Flannel or toweling was used for spacing or "build-up."

The averages of the six observations with cuff application are given in table 1.

When application was made by the electromagnetic induction method, double thicknesses of toweling were used to separate the five turns of cable, which were wound around the thigh. The treatment time was twenty minutes and the current intensity was governed by the patient's tolerance. The averages of six observations with coil technic are given in table 2.

The results indicate that the temperature rise is considerably above what can be expected from conventional diathermy, which has been adopted as a minimum standard of acceptance.

Evidence has been submitted by the firm to substantiate the efficacy of this unit for the administration of hyperpyrexia.

The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is much less than with conventional diathermy.

The machine was installed in a clinic acceptable to the Council and operated under actual clinical conditions. It was reported as giving satisfactory service.

In view of the favorable report based on the performance of this unit when cuff and coil electrodes are used, the Council on Physical Therapy voted to include the Hogan Super-Brevatherm Short Wave Diathermy Unit, Model 8901, in its list of accepted devices.

1. Hogan Super-Brevatherm Short Wave Diathermy Unit, Model 8898, Acceptable, J. A. M. A. 106:2148 (June 20) 1936.

**Society News.**—A tricounty medical society was organized at a meeting in Ahoskie in November, representing Hertford, Bertie and Gates counties. Dr. Louis K. Walker, Ahoskie, was made president and Dr. Thomas G. Faison, Winton, secretary. —Dr. Wingate M. Johnson, Winston-Salem, addressed the Rowan County Medical Society, Salisbury, December 3, on "The Trend Toward Socialized Medicine in the United States." —Dr. George F. Cahill, New York, addressed the Guilford County Medical Society, Greensboro, December 8, on "The Present Value of Roentgenograms in Urinary Tract Injuries."

**Hospital News.**—A new building for tuberculous patients recently completed at the State Hospital for Negro Insane, Goldsboro, has been named the Linville Building in honor of Dr. W. Clinton Linville, who has been superintendent of the institution for the past ten years. The new building accommodates 150 patients. —Recent guest speakers at Duke Hospital, Durham, have been Drs. Albert Graeme Mitchell, Cincinnati, on endocrinology; Sanders L. Christian, U. S. Public Health Service, Washington, D. C., the history and functions of the service, and George W. McCoy, director of the National Health Institute, Washington, recent advances in epidemiology.

## OHIO

**Personal.**—Dr. John B. Kistler, Newcomerstown, has been appointed medical inspector in the division of communicable diseases of the state department of health.

**Dr. Schiller to Lecture in Toledo.**—Dr. Walter Schiller of the University of Vienna will be the lecturer for the thirteenth annual postgraduate course presented by the Academy of Medicine of Toledo during the week of January 11. Dr. Schiller's topics will be: obstetric pathology, gynecologic pathology, including early diagnosis of ovarian tumors, obstetric and gynecologic endocrinology.

**Society News.**—Dr. Roll H. Markwith, Akron, was elected president of the Ohio Federation of Public Health Officials at the recent conference in Columbus. —Dr. Chevalier L. Jackson, Philadelphia, addressed the Marion Academy of Medicine and the Marion chapter of the Pan American Medical Association, December 1, on indications for bronchoscopy. —Dr. Roscoe R. Graham, Toronto, addressed the Cleveland Academy of Medicine, December 18, on duodenal ulcer. —Dr. George H. Belote, Ann Arbor, Mich., addressed the Toledo Academy of Medicine at its annual joint meeting with the Toledo Dental Society, December 4, on "Lesions of the Mouth."

## OKLAHOMA

**Society News.**—Dr. Arthur C. Pattison, Oklahoma City, addressed the Garfield County Medical Society, Enid, November 27, on surgery of the chest. —Drs. Harry S. Price and Julia Florence W. Austin, Dallas, Texas, addressed the Payne County Medical Association in Cushing, November 19, on endocrinology. —Dr. Robert C. Sullivan, Ardmore, among others, addressed the Carter County Medical Society in Ardmore, November 9, on fractures of the hip joint and of the wrist. —At a meeting of the Kay County Medical Society in Tonkawa, November 19, the speakers were Drs. Philip M. McNeill and Herbert D. Collins, Oklahoma City, on pneumonia and appendicitis, respectively.

## PENNSYLVANIA

**Society News.**—Dr. Harold L. Mitchell, Pittsburgh, addressed the Washington County Medical Society, Washington, December 9, on "Vascular Diseases of the Nervous System." —Dr. William James Gardner, Cleveland, addressed the Lawrence County Medical Society, New Castle, December 3, on disease conditions in the head.

**Study of Medical Care for the Indigent.**—Following the abandonment of emergency medical relief service in September, 1936, appointment of a commission to study medical care of the indigent and draw up a policy for subsequent development was recommended by representatives of the professional groups participating in medical relief. With the approval of the Pennsylvania Public Health Legislative Conference and the board of trustees of the Medical Society of the State of Pennsylvania, the following representatives of the state organizations comprising the legislative conference were appointed to the commission:

Dr. George Harlan Wells, Philadelphia, representing the Homeopathic Medical Society of Pennsylvania.  
Dr. Chauncey L. Palmer, Pittsburgh, Medical Society of the State of Pennsylvania.  
Charles H. Hollister, D.D.S., Pennsylvania State Dental Society.  
Dr. Charles J. Hemminger, Somerset, Pennsylvania State Eclectic Medical Society.

Mr. John C. Walton, Philadelphia, the State Pharmaceutical Association.

Mr. Melvin L. Sutley, Drexel Hill, Hospital Association of Pennsylvania.

Miss Netta Ford, R.N., York, Pennsylvania State Nurses Association.

Dr. Samuel H. Brown, Philadelphia, has been chosen as director of the survey, from which recommendations will be developed for presentation to the state legislature not later than April 1.

## Philadelphia

**County Society Sponsors a Public Meeting.**—The Philadelphia County Medical Society invites the public to attend a meeting January 27, at which Dr. Charles Gordon Heyd, New York, President of the American Medical Association, will speak on "Organized Medicine and the Public" and Dr. Maxwell J. Lick, Erie, president of the Medical Society of the State of Pennsylvania, on "Dramatic Episodes of Medicine."

**Society News.**—Drs. Henry K. Sangree and Margaret C. Sturgis addressed the Philadelphia Urological Society, December 21, on "Sterility Studies in the Male, with Their Practical Application" and "Sterility Studies in the Female" respectively. —A symposium on diseases of the colon will be presented at the meeting of the Philadelphia County Medical Society, January 13, by Drs. William A. Swalm, Bernard P. Widmann, Russell S. Boles and Henry L. Bockus.

## Pittsburgh

**Personal.**—Dr. Charles E. Ziegler has been appointed professor of obstetrics at the University of Pittsburgh School of Medicine to fill a vacancy created in 1933 by the retirement of Dr. Harold A. Miller. —Lawrence Wade Bass, Ph.D., recently director of research for the Borden Company, New York, has been appointed assistant director of Mellon Institute of Industrial Research. Dr. Bass received his doctorate at Yale University in 1922 and later studied abroad. From 1925 to 1927 he was an assistant and for the next two years an associate at the Rockefeller Institute for Medical Research, New York. From 1929 to 1931 he was associated with Mellon Institute as executive assistant.

## TENNESSEE

**Society News.**—Dr. William D. Stinson, Memphis, among others, addressed the Dyer, Lake and Crockett Counties' Medical Society recently on "Focal Infection in the Nasopharynx." —Drs. Roderick Heffron, Boston, and James K. Hall, Richmond, Va., addressed the Sullivan-Johnson Counties Medical Society in Bristol on "Serum Treatment of Lobar Pneumonia" and "Functional Nervous Diseases" respectively. —Dr. Edward L. Turner addressed the Davidson County Medical Society, Nashville, November 3, on "A Common Lesion of the Cervical Spine Responsible for Segmental Neuritis."

## TEXAS

**Dallas Clinical Society Spring Conference.**—The ninth spring clinical conference sponsored by the Dallas Southern Clinical Society will be held at the Adolphus Hotel, March 15-18. Guest speakers will include Drs. George E. Fahr, Minneapolis; Elmer L. Sevringhaus, Madison, Wis.; William F. Rienhoff Jr., Baltimore; Thomas G. Orr, Kansas City, Mo.; Joe V. Meigs and Charles F. McKhann, Boston; Francis E. Senear, Charles M. McKenna and William J. Dieckmann, Chicago; William Mithoefer, Cincinnati; Walter I. Lillie, Philadelphia, and Chauncey D. Leake, Ph.D., San Francisco.

## WASHINGTON

**Seminar in Internal Medicine.**—Dr. Goronwy O. Brown, St. Louis, conducted a seminar in internal medicine at the Seattle General Hospital, December 29-31. His subjects were primary anemia, epidemic encephalitis, liver and gallbladder problems. At a dinner at the Rainier Club Wednesday evening he spoke on "Sugar Tolerance Studies with Particular Reference to the Findings in Epilepsy."

**Changes in Health Officers.**—Dr. James P. Mooney, Ellensburg, has resigned as health officer of Kittitas County and has been succeeded by Dr. Samuel M. Wendt, Ellensburg. Dr. Robert J. Skaife, Colfax, has resigned as health officer of Whitman County, after holding the position twenty years. Dr. John A. Kahl, Vancouver, has been appointed health officer of Clark County, succeeding Dr. Clyde B. Hutt, Vancouver, who has entered private practice.

**Society News.**—Dr. Barnet E. Bonar, Salt Lake City, presented a motion picture on fetal respiration at a meeting of the Spokane County Medical Society, December 10, and Dr. James D. Edgar, Spokane, discussed early diagnosis of

for heart disease are given greater weight than cardiac conditions. This fact produces a trend contrary to the other.

Hedley suggests that the classification of deaths from heart disease be modified to record the deaths on an etiologic basis in a manner not conflicting with the provisions of the International List of Causes of Death. The gist of the plan is that, in addition to tabulating heart disease under the existing titles of the International List, deaths due to various etiologic types of heart disease be placed in unofficial subtitles, so as to determine more nearly the causes of death. The use of an etiologic system will assure the practitioner that death certificates are tabulated more nearly as intended. It is further suggested that an additional factor of accuracy would be to allow physicians greater latitude in assigning causes of death when there is insufficient evidence to justify more exact diagnosis.

Although this study is offered as in no way a final solution of the problem, it makes increasingly obvious the unsatisfactory nature of present heart disease mortality statistics. Certainly, if the statistics are to be of real value, improvement in recording is highly necessary. As an attempt in this direction, this study by Hedley deserves immediate consideration.

#### THE CONFERENCE ON SYPHILIS

More than five hundred persons responded to the call of Surgeon General Thomas Parran of the United States Public Health Service for a three day conference in Washington last week on the control of venereal diseases, especially syphilis. Representatives of the American Medical Association, officers of state medical societies and practicing physicians attended, as well as health officers and social service workers. The conference was asked to consider the question of venereal disease control from six principal points of view. The reports that were adopted by the conference as a whole on the third day were in substance as follows:

1. Estimates were presented of the prevalence of syphilis in the United States. A minimum of 681,000 new cases of syphilis was declared to be the probable annual incidence of the disease. Prevalence in the population as a whole was estimated variously at from 5 to 10 per cent of the population, including syphilis in all its stages from initial infection to the late sequelae. It was recognized especially that all statistical data with relation to syphilis and the other venereal diseases are tentative and inadequate and that there is necessity not only for more accurate gathering of statistics but for research into possible statistical methods which might be applied to the problem of ascertaining the incidence, prevalence, trends and economic aspects of the venereal diseases.

2. The section on the public health control of syphilis stressed the necessity for carrying treatment facilities

to all persons of all economic strata. Emphasis was placed, however, on the fact that no desire existed on the part of the public health officials to undertake the treatment of all cases of syphilis at public expense. It was declared that whenever and wherever possible patients should be treated by family physicians in the usual manner and that the personal relationship of patient to physician should be maintained wherever possible. The section reported that in its judgment the treatment of indigent and borderline patients in clinics would be a necessity. Adequate social service for the clinic to ascertain the degree of ability to pay was dealt with in another section. Reporting of the venereal diseases was stressed as a necessity in their control. The section recommended that the Surgeon General request reporting by name and address as in the case of other communicable diseases. This recommendation of the section was opposed from the floor of the conference and ultimately was amended to read in effect that reporting by name and address be encouraged where practicable, but that in other localities reports by number or by initials and date of birth be accepted for the present in order to allow opportunity for overcoming the well known reluctance of physicians to report venereal diseases by name. The necessity for furnishing laboratory service gratis and for the free distribution of drugs needed in the treatment of venereal diseases through public health authorities was stressed. A recommendation to the effect that prophylaxis be regarded as an integral part of the syphilis program was opposed from the floor. The opposition, however, was overwhelmingly defeated and the report of the section therefore included the recommendation that prophylaxis be included in the antisiphilic program.

3. The section on treatment presented a voluminous report, of which the salient points were the importance of early treatment and the treatment of the pregnant syphilitic woman. Emphasis was laid on the necessity for continuous treatment except in the case of late syphilis in persons of middle age or beyond; on the importance of confining the distribution of drugs through public health departments to established preparations—namely, the arsenicals, bismuth compounds, mercury ointments, and possibly iodide preparations.

4. The section on medical follow up of the venereal disease patient reported the importance and necessity for follow up in certain types of cases. Much follow-up work can be prevented by efficient, courteous and expeditious handling of patients on their first visit to the clinic. Emphasis was also laid on the necessity for adequately trained nurses, either medical social workers or public health nurses, for follow-up procedures. Follow up is more effective if done by a person already known to the patient through previous contact. Where personnel needs to be augmented in order to take in a program of venereal disease follow up, it is better to extend the general staff to absorb the venereal dis-

### LONDON

(From Our Regular Correspondent)

Nov. 28, 1936.

#### The National Physique

In the house of lords an important debate took place on the national physique, in which the two medical peers took part. Lord Dawson said that the question transcended all political and social divisions. Britain was not a deteriorating nation, but in our midst there were seeds of deterioration which might quickly be multiplied. The average boy and girl today were taller and heavier than those of former generations, but mere bulk of frame was not evidence of fitness. We were now reaping not only the advantages of medical science and social services but also the disadvantages. A high birth rate and a high death rate brought about a substantial elimination of weaklings. Now that the death rate was falling steadily, nature's method had been rendered nugatory. Weaklings were not eliminated to anything like the same extent. They were given maintenance and treatment and were able even to marry on their maintenance allowance. We were preventing the death of the unfit and had not planned any adequate substitute. It was essential to promote the fit, and on the other hand to take care of the inherently unfit and prevent them from vitiating the race. The unfit should be given a kindly simple shelter, but no effort should be made to raise them above their biologic level, for this would involve the risk of vitiating the race. We had 250,000 mental defectives able to hold their own economically, but unfit as parents. Physicians were being exhorted to think in terms of prevention, and they were striving to do so. Why were they not allowed by law to sterilize and so prevent the birth of children to defectives? He also advocated better physical training. We wanted a British standard of training in our schools. The physical trainer, the mental trainer and the physician should act together. What was gained at school was often lost afterward, because there were no facilities for the youth of the nation to carry out physical exercises. Modern mechanization, where no use was made of the physical attributes of the body, was producing deterioration of physique.

Lord Horder said that fitness for living, fitness for working and fitness for fighting, if it must be, could not be obtained by physical training alone. There were more basic things—food, shelter, air and leisure. Advertisement of what this nation had done in these directions would be wholesome for our self respect and be salutary reading for some other nations, but much remained to be done. Food was fundamental in all questions of fitness. Look after the accessibility of food, and nutrition would look after itself. He was not appalled by the question of expense, if the money was wisely spent on enduring benefits. We had kept the greatest of all our assets—individual liberty. One could not really plan for individual fitness; even the best physician could not make his patients healthy. He approved of centralized physical training, but he hoped that our people would not be regimented. If they were given security and sustenance, their sturdy common sense would do the rest.

Replying for the government, Earl De la Warr, undersecretary for the colonies, said that the house was apparently agreed that there was need for drastic attack on health problems. The government would mobilize voluntary effort plus the local authorities and would help and encourage them to give facilities for the promotion of greater health. If they could provide playing fields and swimming pools and the right type of instructor, these would be used. As to nutrition, if the right food and the right knowledge were available immense strides could be made.

#### Protection for Retired Physicians

It has been a matter of concern for some time to the Medical Defense Union that on retiring from practice physicians resign their membership, in spite of a letter pointing out that even after retirement they are still liable to attack for alleged misdeeds during practice. The union has therefore made a proposal offering special terms to retiring physicians. Those who have been members for ten years or less may become life members on payment of \$15; those who have been members for more than ten years but less than fifteen, on payment of \$10, and those who have been members for more than fifteen years, on payment of \$5. This arrangement will cease if the member should reengage in practice in any form other than a casual attendance dictated by the circumstances of an accident or emergency. If he reengages he must become reinstated as an ordinary member by paying the usual annual subscription until such time as he again retires, when he will become a life member without further payment. The records of the society show several cases in which an attack was made on a physician after several years of retirement—in one case as long as twenty-two years. But according to recent legislation such attack is now barred after a period of six years from the occurrence.

#### "Associate Members" of the Medical Association

A need has arisen to meet the needs expressed by certain oversea branches of the British Medical Association for the creation of a class designated "local members." These would be recruited from members of the local profession who are not registrable in Great Britain and therefore cannot become ordinary members of the association. The reasons for the proposal are apparently that the branches should have some control over these practitioners and also that the standard of the profession would be improved. The privileges of such members would be restricted to the receipt of the *British Medical Journal* and attendance at the meetings of the branch. They would have no voting rights. The organization committee of the association thinks that the proper name for such members is "associates." Amendments to the articles and by-laws of the association have been drafted to empower branches to elect as "associates" physicians who are not registered or registrable in Great Britain, the branch electing them to determine what privileges should attach and what subscriptions should be payable. It is felt that this provision might assist in the solution of some of the difficulties at present being experienced in India. The council of the association has agreed that a recommendation on these lines should be made to the representative body. In the case of the Sudan branch it has agreed that, pending settlement of this larger question, the branch should be allowed to elect as a "special class" physicians not registrable in Great Britain, their privileges being to attend addresses and take part in technical discussions and to receive the *Journal*, the subscription not to exceed \$7.50 a year, of which not more than \$6 would be payable to the central council. Inquiries on these lines have also been received from Aden and Palestine. The problem is due to the existence overseas of physicians legally qualified to practice in their localities but whose qualifications are not registrable in Great Britain and who therefore cannot join the British Medical Association as ordinary members according to its articles of association.

#### The Smoke Evil

A proposal for new legislation for smoke prevention has been brought forward by the National Smoke Abatement Society, at which the Royal Sanitary Institute, the Institute of Builders and the Department of Scientific and Industrial Research were represented. In his address the chairman said that the only effective method of controlling smoke from non-industrial premises was by the establishment of smokeless zones

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ALABAMA

**Society News.**—At a meeting of the Northwestern Division of the Medical Association of the State of Alabama in Jasper, January 8, the following speakers participated: Drs. Daniel C. Elkin, Atlanta, "Diagnosis and Treatment of Wounds of the Heart"; Audiss M. Walker, Tuscaloosa, "Sinuses, from Today's Aspect"; William W. Alexander, Florence, "Postparalytic Prior Poliomyelitis"; Ollie P. Board, Birmingham, "Treatment of Peripheral Vascular Disease," and Lewis C. Davis, Gordo, "Treatment of Lobar Pneumonia." Dr. Charles B. Jackson, Jasper, gave the invocation.

### ARKANSAS

**Society News.**—Drs. Charles T. Chamberlain and Arthur F. Hoge, Fort Smith, presented a symposium on gallbladder disease before the Sebastian County Medical Society, November 10.—At a meeting of the Mississippi County Medical Society in Blytheville, November 10, the speakers, all of Memphis, were Drs. Michael J. Roach Jr. on "Toxemias of Pregnancy"; Samuel Blackwell, "Nonsurgical Treatment of Gallbladder Disease," and Chester D. Allen, "Urethral Stricture."—The Randolph-Lawrence County Medical Society was addressed at Walnut Ridge, November 10, by Drs. Henry O. Walker, Newport, on "Acute Gangrene of the Leg" and Ellis L. Gibson, Alicia, "Infections."—At a meeting of the Benton County Medical Society in Rogers, November 12, the speakers were Drs. Sam Grantham Jr., on "Intestinal Obstruction: Diagnosis and Treatment" and Paul W. Walker, "Chronic Prostatitis: A New Method of Treatment"; both are of Joplin, Mo.—Dr. William R. Brooksher, Fort Smith, addressed the Washington County Medical Society at Fayetteville, December 1, on "Modern Trends in Roentgen Therapy."

### CALIFORNIA

**Speakers' Bureau Organized.**—The Los Angeles County Medical Association has created a speakers' bureau. Officers are Drs. Paul A. Quaintance, chairman; Lewis A. Alesen, vice chairman, and Charles E. Futch, secretary.

**Society News.**—Dr. Arthur E. Hertzler, Halstead, Kan., addressed the Los Angeles Surgical Society, December 11, on "Differentiation Between Toxicity of Degeneration and Toxicity of Hyperplasia of the Thyroid Gland."—Dr. Donald D. Lum, Alameda, among others, discussed "New Developments in the Treatment of Meningococcus Meningitis" before the Alameda County Medical Association at its meeting in Oakland, December 21.

**Medical Postage Stamp Exhibit.**—A special exhibit of postage stamps relating to medicine has been arranged in the University of California Medical School Library, according to *California and Western Medicine*. A large part of the exhibit is the property of Karl F. Meyer, Ph.D., San Francisco, director, Hooper Foundation for Medical Research, and includes stamps issued by many countries in commemoration of medical events or physicians of prominence.

### FLORIDA

**Society News.**—At a meeting of the De Soto-Hardee-Highlands County Medical Society in Wauchula, November 10, Drs. W. Wardlaw Jones, Dade City, discussed early pregnancy with special reference to abdominal pains, and Gordon H. McSwain, Arcadia, treatment of burns.—Dr. Gideon Timberlake, St. Petersburg, addressed the Pinellas County Medical Society, December 4, on "Pathology, Symptomatology and Diagnosis of Diseases of the Prostate," and Dr. Arthur J. Logie, Chattahoochee, of the state board of health, outlined plans for an antituberculosis program.

### ILLINOIS

**Quarantined for Influenza.**—The Hines Memorial Hospital at Hines has been placed under quarantine for an indefinite period on account of the prevalence of influenza, it was reported December 30. While there is no outbreak among the

1,750 patients in the hospital, the step was taken as a precautionary measure. During the quarantine, visitors will be admitted only in case of emergency.

### Chicago

**Annual Meeting of Heart Association.**—The Chicago Heart Association will hold its fifteenth annual meeting at the Congress Hotel, January 14. Dr. Thomas Duckett Jones, instructor in medicine, Harvard University Medical School, Boston, will discuss "The Natural History of Rheumatic Fever and Heart Disease with Especial Reference to Etiology and Prognosis."

**Lectures and Seminars on Psychoanalysis.**—"The History of Medical Psychology" and "The Psychology and Sociology of Suicide" will be discussed in a series of lectures by Dr. Gregory Zilboorg, New York, during the second quarter at the Institute of Psychoanalysis. During the same period a series of lectures and seminars will be offered only for members of the Chicago Psychoanalytic Society and the candidates of the institute. Lecturers will include Drs. Therese Benedek, Thomas M. French and Franz G. Alexander, director of the institute.

**Dr. Irving Cutter Appointed Medical Director of North Western Railway.**—Dr. Irving S. Cutter, since 1925 dean of Northwestern University Medical School, Chicago, and since 1934 health editor of the *Chicago Tribune*, has been appointed medical director of the Chicago and North Western Railway. He has also been medical director of Passavant Hospital since 1928. Dr. Cutter will continue to hold his other positions. He graduated from the University of Nebraska College of Medicine, Omaha, and was identified with his alma mater from 1910 to 1925, holding the deanship for the years 1915-1925. Dr. Victor H. Horning has been named assistant to Dr. Cutter in his new position.

**Branch Meetings.**—Dr. Francis D. Murphy, Milwaukee, addressed the Englewood Branch of the Chicago Medical Society, January 5, on "Management of Cardiovascular Renal Diseases."—The North Shore Branch devoted its meeting, January 5, to case reports by the staff of Swedish Covenant Hospital: Drs. Ralph A. Davis, Raymond F. Elmer, Oscar T. Roberg, Eric Oldberg and Willard Van Hazel.—At a meeting of the West Side Branch, December 17, Drs. Eugene T. McEnery and Paul H. Holinger spoke on bronchiectasis in children.—Dr. Henry F. Helmholz, Rochester, Minn., discussed "Mandelic Acid in the Treatment of Urinary Infection in Childhood" before the North Side Branch, January 7, and Dr. Charles W. Mayo, Rochester, "Digestive Qualifications of Man."

### INDIANA

**Motion Picture Operator for State Health Department.**—To meet the increased demands of health organizations for visual education programs, the Indiana State Department of Health has secured the full time services of a motion picture operator to assist in projecting lantern slides and other health programs. Mr. Noble J. Smallwood, the operator, will be available to all groups interested in health programs; there will be no charge for the service. The state department asks that requests be sent in at least two weeks in advance of the date of the program.

**Society News.**—Surgery in the treatment of pulmonary tuberculosis was discussed at the meeting of the Indianapolis Medical Society, December 22, with Drs. Charles J. McIntyre, James H. Stygall and Frank B. Ramsey as the speakers.—Dr. Verne K. Harvey, Indianapolis, discussed health aspects of the Social Security Act before the Vigo County Medical Society, December 8.—At a meeting of the Kosciusko County Medical Society in Warsaw, December 8, Dr. George L. Kress, Warsaw, discussed relief of pain in labor.—Drs. Clarence L. Bock and Theodore R. Hayes, Muncie, addressed the Jay County Medical Society in Portland, December 4, on bladder neck obstruction.—The medical and bar associations of Jasper and Newton counties met in Rensselaer, December 3; the speaker was Mr. Albert Stump, Indianapolis attorney.—Dr. Arthur B. Richter, Flora, discussed treatment of nephritis before the Carroll County Medical Society in Delphi, December 10.—At a meeting of the Fort Wayne Medical Society in Fort Wayne, December 15, Dr. David I. Schwartz, Fort Wayne, presented a paper on "Treatment of Acute Hematogenous Osteomyelitis."—Drs. Frank W. Cregor and John E. Dalton, Indianapolis, conducted a clinic on some of the commoner skin diseases before the Sullivan County Medical Society in Sullivan, December 2.

### Death of Dr. Amédée Borrel

American bacteriologists who have studied at the Pasteur Institute here will regret to learn of the death of Dr. Amédée Borrel at the age of 69 years. Since leaving Paris he had occupied the chair of bacteriology and hygiene at the University of Strasbourg. In 1892 he entered the laboratory of Prof. Elie Metchnikoff at the Pasteur Institute of Paris and soon became associated with Professor Roux in the courses in bacteriology in which many foreigners participated. Later (1894) he became one of the chief co-workers of Pasteur and with Calmette was the first to prepare a serum against the plague. In 1898 he published an important article on cerebral tetanus and proposed the injection of antitetanic serum by the intracerebral route. Since then Borrel had made a number of important contributions on experimental tuberculosis, tissue culture and the rôle of parasites in certain cancers. His work on the last named was confirmed by Fibiger and Bridie.

### BERLIN

(From Our Regular Correspondent)

Nov. 2, 1936.

#### Convention of German Physicians and Scientists

The ninety-fourth annual convention of the Gesellschaft Deutscher Naturforscher und Aerzte was held in September as usual at Dresden. Each of these conventions is accustomed to have a patron saint, usually selected from the history of medicine; this congress met under the protection of C. G. Carus, a physician, scientist and philosopher who flourished during the first half of the nineteenth century and who was the most daring representative of the "romantic medicine" of that period. The school of "biologic medicine," which exercises so powerful an influence in contemporary Germany, sees in Carus one of its most important precursors.

Most impressive was the address of this year's president, the Berlin surgeon Professor Sauerbruch, on "The Problems of Medicine and of Natural Science." Within the scope of Sauerbruch's remarks were included all the controversial points and problems that beset the German medical world today. In addition he took up the question of the place of the university and of natural science in the new state, with particular reference to the investigation of causes. This speech assumed the character of a confession of faith. Sauerbruch, for example, called attention to the fact that the criticism of the universities and their methods which was rife during the first period of National Socialist domination has now happily begun sharply to subside. The distinctive character of scientific work is now beginning to be understood once more. "Accordingly, now is the time to reestablish that state of tranquillity which is now and always will be the fundamental condition for scientific activity." And Sauerbruch uttered the further significant remark: "Reason alone is not enough; it must be supplemented by a reaction of the spirit to the unconscious patterns of nature." Then in conclusion he warned against falling into the reverse error. "The physician senses the unity of the mysterious forces of nature but the scientific disciplines he feels as particulars. From the moment he seeks to create one special science of the latter, all will be false. . . . A new medicine in the sense of something that has never yet existed is certainly not to be recommended." The regular physicians through understanding of Nature Medicine have come to adopt the methods of the latter in conjunction with older procedures. "Meanwhile, to obtain accurate results, we need data that can only be acquired by exact observation." He then quoted a dictum of Paracelsus, who is so frequently cited as an authority by present-day Germans, and this particular quotation must have caused no end of surprise among the audience or at least among the leading authoritative physicians present; it ran: "If thou wouldst not learn aught of the science of medicine,

thou art an enemy of the people." Sauerbruch went on to formulate the principle of scientific freedom and self reliance as follows: "With service to the people alone, science cannot exhaust herself. Her domain is not only of this world. The temporal and the eternal must be harmoniously combined in science; only then can science adhere to her unchanging principle: to seek the truth with sincerity." Sauerbruch closed his address with a "final confession of faith," a word to the youth of the universities: "Work and experience," he said "must be tested and coordinated by the spirit and the understanding. The concept of the whole is designated by that somewhat overworked term 'weltanschauung.' But only the tried and tested man of maturity can be said to possess a weltanschauung and such an acquisition is not within the reach of the young. Youth possesses openmindedness, energy and hope. But the capacity for working, knowledge and experience, the insight into those realms of science that are to be comprehended only by the intellect, are also necessary." Old and young must collaborate in the performance of the most difficult tasks and deeds of genuine service.

The foregoing significant and courageous utterance, a confession of faith in the true scientific spirit by a leader of science has produced a tremendous understandable sensation both in Germany and abroad, particularly since such candid expression of opinion has become a rarity within the Third Reich. This speech of Sauerbruch's has received only fleeting mention in the German medical press. A few vague comments have appeared which can scarcely be said to show any sympathy for the main thesis of Sauerbruch's courageous utterance and which in some instances flatly reject it (as in the *Deutsches Aerzteblatt*, official organ of the entire German medical profession). Sauerbruch's address stands out as the "high spot" of this convention.

#### MEDICINE AND BIOLOGY

The topic of the first general session was "Medicine and Biology." Ludwig Aschoff of Freiburg-in-Breisgau provided a discussion of pathology and biology in which he referred to the fact that the demarcations between animate and inanimate matter have been obliterated by advances in the knowledge of the type of ultramicroscopic virus and chemical agents which form in the nuclei of cells and which conduce to cancer. Pathology, however, ought not to be regarded as a purely natural science, since the concept of evaluating life as healthy or diseased must underlie the pathologist's exact observation of phenomena. Aschoff believes that, owing to the brevity of the period of academic preparation, instruction in the recognition of diseases is of more importance than instruction in their treatment (this opinion of Aschoff's is not subscribed to by pathologists generally).

Among other speakers on the topic was Karl Kötschau of Jena, who once again said his say on behalf of Nature Medicine.

In the medical section, Franz Volhard of Frankfurt-on-the-Main as an internist and Rudolf Thiel also of Frankfurt as an ophthalmologist discussed the importance of visual examination for the understanding of disturbances due to hypertension and to diseased kidneys.

In the section on internal medicine the question of hyperthyreosis was the principal topic. Erwin Gohrbandt of Berlin pointed out that preliminary treatment with iodine has made possible a considerable decrease in the postoperative mortality. If preliminary iodotherapy has been possible, Gohrbandt performs a one-stage intervention; in the absence of this preliminary treatment a two-stage operation is performed. Sudden deaths in improperly prepared operative cases he attributes to a rapid withdrawal of flushed out toxin (somewhat as in morphinism and alcoholism).

## MINNESOTA

**Society News.**—The Hennepin County Medical Society was addressed in Minneapolis, December 16, by Edmund V. Cowdry, Ph.D., St. Louis, on "Pathogenic Viruses," and, December 9, by Drs. Charles D. Creevy and James A. Johnson on "Present Status of Transurethral Resections" and "Treatment of Carcinoma of the Rectum by Electrocoagulation" respectively.—Dr. William L. Benedict, Rochester, addressed the Minnesota Academy of Medicine in Minneapolis, December 9, on "Episcleritis in Relation to Disease of the Pelvic Organs," and Dr. Alfred Hoff, St. Paul, "Agranulocytosis."—Dr. Edwin A. Kilbride, Worthington, was elected president of the Southwestern Minnesota Medical Society at its annual meeting in Worthington, November 16; Dr. Charles L. Sherman, Luverne, vice president, and Dr. Hermann De Boer, Edgerton, secretary.

## MISSISSIPPI

**Society News.**—The Clarksdale and Six Counties Medical Society was addressed in Clarksdale recently by Drs. Wesley W. Hall, Shelby, on ruptured tubal pregnancies; Winston C. Pool, Cary, coronary artery disease, and Henry C. Ricks, Jackson, poliomyelitis. Dr. Hiram W. Kostmayer, New Orleans, addressed the banquet session on "Endocrine Therapy in Gynecology."—At a meeting of the Coahoma County Medical Society and the staff of Clarksdale Hospital in November, Dr. William P. Warfield, Clarksdale, discussed infections of the upper respiratory tract in infants and children.

## MISSOURI

**The Hodgen Lecture.**—Dr. Edward D. Churchill, John Homans professor of surgery, Harvard University Medical School, Boston, will deliver the annual Hodgen Lecture before the St. Louis Medical Society, January 12. His subject will be "Surgery of the Parathyroids." The lecture is under the auspices of the St. Louis Surgical Society and the Medical Fund Society.

**Society News.**—The St. Louis Medical Society was addressed, December 15, by Drs. Benjamin H. Orndoff, Chicago, on "Value of the X-Rays and Radiopaque Oils in the Detection of Pathology of the Cervix, Corpus Uteri and Oviducts," and Henry Schmitz, Chicago, "Prophylaxis and Early Diagnosis of Cancer of the Cervix." The society met jointly with the ophthalmic section, December 22, in a program commemorating the eightieth anniversary of Albrecht von Graefe's discovery of the efficacy of iridectomy for glaucoma. Guest speakers were Drs. William F. Petersen on "Glaucoma: Autonomic Integration and Environment" and Michael Goldenburg, who presented the ophthalmic discussion; both are of Chicago.—Dr. Iago Galdston, New York, addressed the thirtieth annual meeting of the Tuberculosis and Health Society of St. Louis, December 7, on "Science versus Human Beings."—At a joint meeting of the St. Louis Dental Society with the St. Louis County Medical Society, January 4, Ura G. Rickert, D.D.S., professor of diagnosis, dental therapeutics and radiology, University of Michigan School of Dentistry, Ann Arbor, spoke on "Twenty Years of Study of Rheumatic Diseases from the Dental Viewpoint."

## NEBRASKA

**Society News.**—Dr. Walter M. Simpson, Dayton, Ohio, addressed the Omaha-Douglas County Medical Society, December 8, on "Experiences in Artificial Fever," and Dr. Abram E. Bennett, Omaha, reported the progress of a fever therapy research project at the University of Nebraska College of Medicine.

## NEW MEXICO

**Personal.**—Dr. Elias T. Hensley, Portales, has been appointed a member of the state board of medical examiners to succeed the late Dr. Frank H. Johnson, Carrizozo.

## NEW YORK

**Dr. Sakel Lectures on Hypoglycemic Treatment of Schizophrenia.**—Dr. Manfred Sakel, Vienna, is giving a six weeks course of instruction at the Harlem Valley State Hospital, Wingdale, in the hypoglycemic treatment of schizophrenia, at the invitation of Dr. Frederick W. Parsons, commissioner of the state department of mental hygiene. Dr. Parsons has authorized each state hospital to send a physician to the Harlem Valley State Hospital for instruction in the technic of the new therapy. A paper on this subject by Dr. Julius Steinfeld,

Peoria, Ill., appears in this issue of THE JOURNAL, page 91, and one by Dr. Bernard Glueck, Ossining, was published Sept. 26, 1936, page 1029.

## New York City

**Theobald Smith Lecture.**—Dr. Hans Zinsser, Charles Wilder professor of bacteriology and immunology, Harvard Medical School, Boston, will give the annual Theobald Smith Lecture of the New York Society of Tropical Diseases, January 22, at the Cornell University Medical College, on "Rickettsia Diseases."

**Hospital News.**—A new physical therapy unit was opened recently at the New York Post-Graduate Medical School and Hospital with Dr. John D. Currence as its head. The unit includes a special tank for underwater therapy.—Dr. Manfred Sakel, Vienna, gave a lecture at Mount Sinai Hospital, November 12, on "Hypoglycemia and Its Therapeutic Effect."

**Faculty Changes at New York University.**—Among recent changes in the faculty of New York University College of Medicine were the following promotions:

Dr. Thomas A. Gonzales, to associate professor of forensic medicine.  
Drs. Milton Helpern and Benjamin M. Vance, assistant professors of forensic medicine.

Dr. James Burns Amberson Jr., professor of clinical medicine.  
Dr. Charles Gottlieb, assistant professor of radiology.  
Dr. Milton Benjamin Rosenbluth, assistant professor of clinical medicine.

Dr. Alfred Townsend Osgood, professor of urology since 1912, was made professor emeritus.

**Lectures by Professor Arcé.**—Dr. Jose Arcé, Buenos Aires, professor of surgery at the University of Buenos Aires and rector of the university, arrived in New York December 15 for a lecture tour as the guest of chapters of the Pan American Medical Association. Dr. Arcé will speak on "Pan American Medicine" before the chapters in New York, Washington, Los Angeles and San Francisco and will also observe methods of teaching graduate physicians. Dr. Joseph Jordan Eller, director general of the association, and Mrs. Eller gave a reception Sunday, December 20, in honor of Dr. Arcé and his party, which includes Drs. Adolfo F. Landivar, Antonio Egeus and Isidro Castillo Odena, all professors of surgery at the University of Buenos Aires.

**Dr. Reynolds Honored.**—The committee on medical education of the New York Academy of Medicine gave a dinner December 7 in honor of Dr. Frederick P. Reynolds, who is retiring from the secretaryship of the committee after several years' service. Dr. Carl Eggers, chairman of the committee, presided at the dinner and those present included twenty-two members of the committee; Major Gen. Charles R. Reynolds, surgeon general, U. S. Army, brother of Dr. Reynolds, and Dr. Mahlon Ashford, who has been appointed to succeed Dr. Reynolds as secretary. Dr. Reynolds spent thirty years in service with the Army Medical Corps, retiring in 1923. He was graduated from the University of Pennsylvania School of Medicine in 1890 and is now 69 years old. In addition to serving as secretary of medical education he was assistant secretary of the academy.

**Society News.**—The Medical Society of the County of New York devoted part of its meeting December 21 to a memorial session in honor of the late Dr. Daniel S. Dougherty, secretary of the society from 1917 to 1936 and director from 1929 to 1936. Dr. Orrin S. Wightman delivered a eulogy. Dr. Charles Gordon Heyd, President of the American Medical Association, made an address on "Organized Medicine" and Dr. Floyd S. Winslow, Rochester, N. Y., president of the Medical Society of the State of New York, on the current activities of that society.—Drs. Frank N. Wilson, Ann Arbor, Mich., and Maude E. S. Abbott, Montreal, will be the speakers at a scientific meeting of the Committee on Cardiac Clinics of the New York Heart Association, January 12, on "The Precordial Electrocardiogram" and "The Clinical Significance and the Differential Diagnosis of the Acyanotic and Cyanose Tardive Groups of Congenital Cardiacs" respectively.—Dr. Robert P. Wadhams was recently elected president of the New York University College of Medicine Alumni, and Dr. James W. Smith, secretary. The next alumni day will be held February 20 at the college.

## NORTH CAROLINA

**Personal.**—Dr. Bennie B. Dalton, Rockingham, has resigned as health officer of Richmond County to enter private practice in Liberty.—Dr. John McCampbell, medical superintendent of the State Hospital, Morganton, has been appointed a member of the state eugenics board, succeeding Dr. W. Clinton Linville, Goldsboro.

three periods in the development of medical literature: mixed literature from 1668 to 1773, general medical literature from 1773 to the first half of the last century, and specialized medical literature from the second half of the last century to the present.

The second official topic was "Social Functions of the Medical Press." Speakers for this topic were Professor Le Sage, of the Union Medicale of Canada, and Dr. Olivaro, who is the author of the constitution of the Association of the Italian Medical Press. The third topic was "Principles of Teaching and of Practicing Medicine." Professor Perez of the University of Rome reviewed the arrangement of medical studies, postgraduate courses and services of sanitation in Italy. When the discussions of the official topics were over the following motions were given: First that Latin and Greek be considered compulsory subjects of medical studies. Second, that postgraduate courses, for obtaining a diploma of specialization, be compulsory for practicing medical specialties.

#### Indexes of Food Consumed

According to statistics of the Istituto Centrale di Statistica, the quantity and variety of food consumed by the average Italian population during the last ten years has improved. The consumption of natural products for every man during a year increased, from 1926 to 1935, as follows: fresh rough vegetables from 40 to 54.4 Kg., fresh fruit from 28 to 37.2 Kg., and acid fruits from 8.6 to 10.9 Kg. The consumption of fresh soft vegetables, fresh fish, milk and milk products increased also. The consumption of milk for every man during a year increased from 1926 to 1935 from 24.6 to 34 liters. The consumption of cereals and meat showed no great changes.

#### Deaths

Prof. Francesco Radaeli, head of the Clinica Dermosifilopatica of the Genoa University and a well known dermatologist, is dead. He wrote important articles on Kaposi's hemorrhagic sarcoma, which he called angio-endothelioma, and on the infectious etiology of pemphigus; also a book on cutaneous diseases, of which four editions have already been published. He was the founder of a clinic in Genoa in which a school of dermatology was established. Several of his pupils in this school are teachers in Italian universities and others are directors in dermatologic clinics.

### NETHERLANDS

(From Our Regular Correspondent)

Nov. 16, 1936.

#### Transmission of Paratyphoid Infection by Ducks

A. Charlotte Ruys in the *Nederlandsch tijdschrift voor geneeskunde* calls attention to the danger of paratyphoid infection transmitted by ducks either through the eggs or through the birds themselves.

The author reports the case of a child stricken with type B paratyphoid after having played with two ducklings, one of which was taken ill and died. The surviving bird was placed under observation at the laboratory and there it remained apparently well for six days. After an examination of the feces had proved negative, the duckling was destroyed. Postmortem examination demonstrated that the animal had been a healthy carrier of *Bacterium paratyphosum B* (Aertrycke). The bacilli were obtained in cultures of the intestinal contents.

Last summer in Amsterdam several cases of food poisoning were reported among families the members of which had partaken of duck soup. In four families investigated there were sixteen cases of poisoning, one fatal. *Bacterium paratyphosum B* (three times of the Aertrycke type and once of the Gaertner type) was detected in the stools of all persons who had ingested the soup. A special investigation proved, moreover,

that the soup had been the sole source of the illness. In each instance it had been allowed to simmer over a slow fire and the boiling process had sufficed to destroy all the pathogenic organisms in the broth, since none were found in the residues examined at the laboratory. But boiling had not sufficed to destroy the bacilli within the flesh of the bird. This duck meat had all been consumed and could not be examined. The author cites a somewhat analogous case in which the ingestion of chicken broth was followed by manifestations of illness. Examination of the broth itself disclosed no pathogenic organisms but it was possible to culture the bacilli from a chicken foot which had remained uneaten and the interior of which was nearly raw.

#### Lead Poisoning and Tobacco

In the *Nederlandsch tijdschrift voor geneeskunde* appears a discussion by Jordans, Zijlmans and Broos of lead poisoning among workers in the tobacco industry. The authors had the opportunity to examine several groups of workers in various cigar factories. The general appearance of a large number of the employees denoted a state of poor health, and this could not be explained on the basis of unfavorable working conditions (the hygiene of cigar factories has undergone vast improvement) or by the fact that this type of employment does not require great physical stamina on the part of the worker (the vast majority of 4,000 cigar makers examined were of sound constitution). Chronic nicotineism was likewise ruled out, as none of the persons observed presented any symptoms of nicotine intoxication. The authors concluded that the workers in question were suffering from lead poisoning, although such an intoxication in connection with the manufacture of cigars had never before to their knowledge been described. Six hospitalized cases are reported in detail. An investigation initiated by the authors demonstrated lead poisoning in at least 25 per cent of all the workers.

The source of this intoxication ostensibly was the sheets of zinc on which the cigars were cut. These sheets contained about 1 per cent of lead. The law should require that these metal sheets be replaced by hard wooden plaques; such a substitution would in no way impede the technical process of manufacture.

#### Mortality Statistics

Statistics recently published by the central statistical bureau show that from 1840-1849 to the year 1934 the death rate declined from 26.56 per thousand of population to 8.41. Such a decrease evidences the effectiveness of public health measures and the improvement of living conditions in the Netherlands.

Fatalities among nurslings now constitute 4 per cent of all recorded deaths. In the decade from 1880 to 1889, 18 per cent of all infants born alive died while still in the nursing stage whereas in 1934 the corresponding figure was 4 per cent. This decline attests the influence of improved infant feeding.

The mortality of infants in 1934 should be considered an all-time low. The birth rate, on the other hand, tends to decline in both urban and rural areas. The various provinces of the kingdom exhibit individual differences in this regard. In the province of Friesland the infant mortality is quite low and 58 per cent of the survivors attain the age of 65. In the province of Limburg, the infant mortality is extremely high and but 40 per cent of the survivors attain the age of 65. The corresponding figure for the entire kingdom is 49 per cent.

Among causes of death tuberculosis no longer plays a preponderant part. Diseases of the heart and blood vessels are on the increase; they cause 14 per cent of all deaths (the result chiefly of the abuse of nicotine and of the nervous spirit of the times). The largest single cause of fatalities is cancer, which was responsible for 15 per cent of all the deaths recorded in 1934.

tumors.—Dr. Goronwy O. Broun, St. Louis, addressed the King County Medical Society, Seattle, December 29, on "Physiology and Pathology of Bone Marrow."—Dr. Woodard A. Niethammer, Tacoma, addressed the Pierce County Medical Society, Tacoma, recently on "Iodine in the Treatment and Prevention of Goiter."—At a recent meeting of the Yakima County Medical Society, Yakima, the speakers, all of whom are of Spokane, were Drs. John B. Plastino on "The Endocrines in Hypertension, Carbohydrate Metabolism and Obesity"; Donald A. Palmer, "Achyilia Gastrica, Pernicious Anemia and Gastric Polypi," and James M. Nelson, "Water Balance and Dehydration in Surgical Patients."

### WISCONSIN

**Society News.**—The Milwaukee County Medical Society and the Milwaukee Health Department sponsored a tuberculosis detection program at the South Division High School, Milwaukee, beginning December 7.—Dr. Wheelan D. Sutliff, Chicago, addressed the Milwaukee Academy of Medicine, December 15, on "Serum Treatment of Pneumonia."—Dr. Fred P. Moersch, Rochester, Minn., addressed the Milwaukee Neuropsychiatric Society, November 19, on "Neuronitis."

### WYOMING

**Special Meeting of Delegates—New President-Elect.**—The house of delegates of the Wyoming State Medical Society, at a special meeting in Casper December 14, chose Dr. Victor R. Dacken, Cody, president-elect of the society to succeed Dr. John R. A. Whitlock, Powell, who died Nov. 23, 1936. Dr. Dacken was graduated from the University of Nebraska College of Medicine, Omaha, in 1919.

### GENERAL

**Society News.**—Dr. Fred W. Bailey, St. Louis, was elected president of the Western Surgical Association at the annual meeting in Kansas City in December. Drs. Owen H. Wangenstein, Minneapolis, and Theodore F. Riggs, Pierre, S. D., were elected vice presidents and Dr. Albert H. Montgomery, Chicago, was reelected secretary. The 1937 meeting will be in Indianapolis.

**Social Hygiene Day.**—The American Social Hygiene Association announces plans for the first "National Social Hygiene Day," which will be observed February 3. The association will hold its annual meeting on that day and the Social Hygiene Council of Greater New York its fifth annual conference. State and community voluntary organizations interested in the control of venereal disease also plan meetings throughout the country. The national association, which has headquarters at 50 West Fiftieth Street, New York, will be glad to assist in the formation of local programs, according to the announcement.

**Radiologists Award Medals.**—At the annual meeting of the Radiological Society of North America in Cincinnati, November 30-December 3, the 1936 achievement gold medals were awarded to Dr. Edwin C. Ernst, St. Louis, and Otto Glasser, Ph.D., Cleveland, in recognition of their work in developing a method of x-ray dosage. Dr. Howard P. Doub, Detroit, was named president-elect and Dr. John D. Camp, Rochester, Minn., was installed as president. Vice presidents elected were Drs. Ellis R. Bader, Cincinnati; Paul F. Titterington, St. Louis, and Robert A. Arens, Chicago. Dr. Donald S. Childs, Syracuse, N. Y., was elected secretary-treasurer. The 1937 meeting will be in Chicago in conjunction with the International Congress of Radiology, September 13-17.

**Changes in Status of Licensure.**—The Eclectic State Medical Board of Arkansas announces the following action:

Dr. Guy I. R. Lawless, formerly of West Memphis, license revoked, November 10, for violation of the Harrison Narcotic Act.

The State Board of Medical Examiners of Florida reports the following:

Dr. Wesley S. Miller, Palatka, license revoked for violation of Harrison Narcotic Act.

Dr. Lemuel A. Carter, Bunnell, license revoked for violating the Harrison Narcotic Act.

The Massachusetts Board of Registration in Medicine announces the following action:

Dr. Henry Daniels, Brockton, license revoked, December 10, for his conviction of the charge of abortion.

Dr. Arthur E. Brides, Stoughton, license suspended for six months, December 10, for gross misconduct in the practice of his profession.

Dr. Barney Edward Sachs, Worcester, license revoked, December 10, because of acting as principal or assistant in the carrying on of the practice of medicine with an unlicensed person.

The Minnesota State Board of Medical Examiners reports the following action:

Dr. Val Do Turner, St. Paul, license revoked, November 7, for referring a woman to an abortionist.

**News of Epidemics.**—More than 700 cases of scarlet fever with four deaths had occurred up to December 29 in an outbreak at Owego, N. Y., first reported December 26. The disease was traced to distribution of raw milk by a dairyman despite the illness of three members of his family. More than fifty cases were reported in Cohoes, N. Y., December 12; fifty cases with one death in New Bremen, Ohio.—An epidemic of smallpox at Dansville, N. Y., is believed to be under control. There were fifty-five cases in Dansville and adjacent communities. About eighty-five cases have occurred in a recent outbreak at Klamath Falls, Ore.—About twenty-five cases of typhoid fever with three deaths were reported from Cecil, Pa., December 8; the infection was attributed to pollution of the water supply. At Page, W. Va., about twenty cases were reported December 17; the source had not been determined.

### CANADA

**Dysentery in Saskatchewan—Twenty-Eight Deaths.**—Ninety-five cases of bacillary dysentery with twenty-eight deaths occurred recently in the McMahon District near Swift Current, Sask., particularly in the Mennonite village of Rosenhof. It is believed that the infection was brought into the community by persons who returned from Mexico.

**Hospital News.**—The Winnipeg General Hospital has received a gift of \$25,000 from Mr. John A. Forlong to provide new x-ray equipment, especially for high voltage therapy, in memory of his wife.—Dr. James Douglas Galbraith, Toronto, physician on a United Church mission boat, the *Thomas Crosby*, has been appointed medical superintendent of the Bella Coala Hospital, Bella Coala, B. C.

**Society News.**—Dr. Louis H. Newburgh, Ann Arbor, Mich., addressed the Academy of Medicine of Toronto, December 8, on "Important Advances in Our Knowledge of Kidney Diseases."—Dr. Allen Y. McNair, Vancouver, addressed the Vancouver Medical Association, December 1, on "Tumors of the Large Bowel." Dr. Lavell H. Leeson addressed the association, November 3, on "Respiratory Infections of Childhood."

### FOREIGN

**Personal.**—Sir Norman P. Walker, Edinburgh, has been reelected president of the General Medical Council of Great Britain for a term ending in 1939.—Dr. Dugald Baird, Glasgow, has been appointed regius professor of midwifery in the University of Aberdeen, succeeding Dr. Robert G. McKerron, resigned.

### Deaths in Other Countries

Sir John Bland-Sutton, consulting surgeon to Middlesex Hospital, former president of the Royal College of Surgeons, the Royal Society of Medicine and the Medical Society of London, died in London December 20, aged 81.

## Government Services

### Fines Imposed Under Poison Act

Ten druggists and paint dealers were recently fined in the District of Columbia for selling caustic or corrosive materials in containers not labeled as the Federal Caustic Poison Act requires. Apparently because all the cases were first offenses the court imposed nominal fines of \$10 after the defendants had pleaded guilty. The prosecutions were based on sales of oxalic acid, acetic acid and ammonia water.

### General Shockley Retires

Brig. Gen. M. Augustus Wroten Shockley, assistant to the surgeon general of the U. S. Army, will retire on his own application, effective February 28, according to the *New York Times*. General Shockley is 62 years of age. He graduated from the Kansas City Medical College in 1898, joining in the same year the Seventh U. S. Voluntary Infantry. He advanced through the various grades in the regular army until he was appointed brigadier general in 1935. He was director of the Field Service and Correspondence School for Medical Officers, U. S. Army, from 1915 to 1917; instructor in the School of the Line and Staff College of the army, 1919-1922, and professor of military hygiene, U. S. Military Academy, 1927 to 1931. He was awarded the Distinguished Service Medal and is an officer of the Legion of Honor of France. He is also the author of the "Outline of the Medical Service of the Theatre of Operations."

## Deaths

**Henry Stanley Plummer** ☉ professor of medicine, Mayo Foundation, Graduate School, University of Minnesota, died, January 1, at his home in Rochester, Minn., of cerebral thrombosis, aged 62. Dr. Plummer was born in Hamilton, Minn., March 3, 1874. He took premedical courses at the University of Minnesota and received the M.D. degree from Northwestern University Medical School, Chicago, in 1898. After practicing medicine in Racine, Minn., from 1898 to 1901, he went to the Mayo Clinic in 1901, where he became chief of the division of medicine. In the Mayo Clinic his genius for organization and his flair for mechanics had the fullest opportunity for development. In the construction of the new clinic building he labored indefatigably and many of the remarkable innovations in efficiency of operation were conceived by him. He was chairman of the Section on Practice of Medicine of the American Medical Association, 1920-1921; a past president of the American Association for the Study of Goiter; member of the American Association for Thoracic Surgery, the Central Society for Clinical Research, Association of American Physicians, Association for the Study of Internal Secretions, Medical Library Association and the American Public Health Association; fellow of the American College of Physicians. He was the author and co-author of numerous articles dealing with the physiology and diseases of the thyroid gland. In 1935 he was awarded the honorary degree of doctor of science by Northwestern University. He was a genial philosopher in medicine, a profound thinker whose views were respected everywhere.

**Samuel William Schapira** ☉ New York; University of the City of New York Medical Department, 1895; member of the American Urological Association; formerly professor of clinical surgery, Fordham University School of Medicine; instructor of genito-urinary diseases at the New York Post-Graduate Medical School, 1903-1913; served during the World War; at various times on the staffs of the Beth Israel Hospital and Dispensary, Sydenham Hospital, People's Hospital and City Hospital, New York, and the Sea View Hospital, Staten Island; aged 64; died, Nov. 21, 1936, of heart disease.

**Arthur Lynn Bryan**, Muscatine, Iowa; University of Illinois College of Medicine, Chicago, 1914; past president of the Muscatine County Medical Society; formerly health officer of Muscatine; on the staff of the Benjamin Hershey Memorial Hospital and formerly on the staff of the Bellevue Hospital; aged 50; died, Nov. 12, 1936, in the Methodist Hospital, Madison, Wis., of heart disease, embolus of the right leg, and gangrene.

**Edward Cary Rushmore** ☉ Tuxedo Park, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886; past president of the Orange County Medical Society and the First District Branch of the Medical Society of the State of New York; health officer; surgeon for the Erie Railroad; medical director of the Tuxedo Memorial Hospital; aged 74; died, Nov. 2, 1936.

**Thomas Hawley Rockwell** ☉ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; for many years chief medical director of the Equitable Life Assurance Society; past president of the Association of Life Insurance Medical Directors of America; aged 71; died, Nov. 2, 1936, in the Fair Oaks Sanatorium, Summit, N. J., of chronic nephritis.

**Andrew MacFarlane** ☉ Albany, N. Y.; Albany Medical College, 1887; past president of the Albany County Medical

Society; formerly professor of physical diagnosis and medical jurisprudence at his alma mater; served during the World War; on the staff of St. Peter's Hospital and formerly on the staffs of the Albany Hospital and the Memorial Hospital; aged 73; died, Nov. 10, 1936, of coronary occlusion.

**Wayland Ray Palmer**, Hollidaysburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1902; past president of the school board; medical examiner for the selective board during the World War; on the staffs of the Altoona and Mercy hospitals, Altoona, and the Nason Hospital, Roaring Spring; aged 59; died, Nov. 7, 1936, at a hunting camp near Petersburg.

**Hugh Owen Jones**, Chicago; Northwestern University Medical School, Chicago, 1902; member of the Illinois State Medical Society; assistant to the president and chief of the medical service, city health department, and formerly assistant and acting health commissioner, and chief of the division of child hygiene; aged 61; died, Dec. 24, 1936, of bronchopneumonia.

**Samuel Boughton Whitman Leyenberger** ☉ Newark, N. J.; Columbia University College of Physicians and Surgeons, New York, 1901; fellow of the American College of Surgeons; on the staff of St. Michael's Hospital and on the adjunct staff of the Presbyterian and the Hospital of St. Barnabas; aged 57; died, Nov. 4, 1936.

**Harold William Reilly**, East Bloomfield, N. Y.; University of Buffalo School of Medicine, 1921; for many years health officer of East Bloomfield; on the visiting staff of the Frederick Ferris Thompson Hospital, Canandaigua; aged 41; died, Nov. 18, 1936, in a hospital at Cleveland, of malignant hypertension following adrenal sympathectomy.

**Thomas Charles Lippman**, Southampton, N. Y.; Cornell University Medical College, New York, 1903; member of the Medical Society of the State of New York; on the staff of the Southampton Hospital; aged 59; died, Nov. 11, 1936, in the New York Post-Graduate Medical School, New York, following an operation for disease of the gallbladder.

**Charles John Haines**, Hallstead, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1925; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Physicians; City

Hospital, of a self-inflicted bullet wound.

**Russell C. in cities. In these, smoke emission should be made a legal offense. The central areas of cities could thus be cleared of smoke emission. They could not yet legislate for the smokeless city as a whole. The same principle could be applied to other selected areas, for example in the vicinity of hospitals, parks, airdromes and architectural monuments. The areas concerned would be mainly occupied by offices and business premises, where the coal fire was almost an anachronism. There need be no difficulty about hotels or clubs, as their cooking was mostly done by gas or electricity. There was already sufficient smokeless fuel on the market to supply open fires in public rooms. There was little hope of legislation for the abatement of smoke from dwelling houses, but the rapidly increasing use of gas and electricity for cooking was diminishing smoke emission from kitchen ranges. The open fire in the sitting room remained the crux of the problem. The popular demand for at least one open fire must be conceded. The line of attack appeared to be elimination by degrees of raw bituminous coal and the substitution of smokeless fuels, to which a slow but definite change was taking place without any compulsion.

#### Bureau to Provide Temporary Substitutes for Practitioners

In France, the interests of the profession are looked after by the Federation of Medical Syndicates or Unions, in which each departmental syndicate has a representative. The federation has recently purchased a building in the center of Paris and has opened an office which will aim to provide practitioners who desire a well qualified licensed member of the profession to take charge of their practice temporarily with all the necessary information. Any practitioner who desires a temporary substitute can obtain one by (1) stating the type of practice (internal medicine, general surgery or surgical specialties) and whether the substitute should be a licensed physician or a student who has passed a sufficient number of examinations to permit serving as a substitute or (2) indicating the location, remuneration and length of time during which the practitioner expects to be absent. The physician or qualified student who wishes to serve as a substitute must file his credentials with the office and agree not to begin practice in a territory that is less (in country districts) than 25 miles away from the place in which he replaces a practitioner. In this way the federation assumes the responsibility of providing substitutes whose records have been thoroughly investigated. This will avoid the complaint now existing of the employment of foreigners who do not have the necessary state license to practice and of medical students who are not qualified to act as substitutes. The work of the federation in relation to its proposed cooperation with the public health authorities has already been referred to. A plea is constantly being made by the secretary of the federation for united efforts on the part of the profession in combating the effort of the present government to create state medicine.

#### A Lecture on Postoperative Thrombosis

In the October 10 *Progrès médical* appears a lecture on postoperative thrombosis delivered in Ghent, Belgium, by Prof. René Leriche of Strasbourg, in which the theory of Havlicek as to the etiology of this complication is discussed. The theory of Havlicek is based on the following:

1. The velocity of the circulation is a function of billions of anastomoses which permit the blood to pass directly from the arteries into the veins.
2. There are innumerable interstitial anastomoses in the liver between the portal vessels and those draining into the vena cava.

3. As the result of exertion in the postoperative period, the blood in the portal vein can flow back into the radicles of the vena cava as far as the femoral vein.

4. The blood in the portal circulation coagulates that in the systemic veins.

5. Postoperative slowing up of the circulation favors coagulation.

6. Postoperative thrombosis is due to the reflux of the blood from the portal circulation into that of the vena cava.

Now Nolf has shown that the blood in the vessels during life contains all the factors necessary for coagulation but that they are in a colloidal state of stability. This means that there is no coagulation within the vessels under normal conditions. Coagulation takes place outside the vessels under the influence of the tissue juices, white blood cells and blood platelets in the presence of calcium or when there is an extreme degree of slowing up or a complete arrest of the circulation. One should not confuse thrombosis and coagulation. Clinicians are not as aware of this as are physiologists. Thrombosis is not an anomaly of coagulation. The two processes are not the same. When a vessel is thrombosed, coagulation is a secondary phenomenon at the site of the thrombosis, the latter being primary. Coagulation is a phenomenon of precipitation, under the form of fibrin, of an albuminous body which is found in the normal blood as fibrinogen, the latter being transformed into fibrin. Thrombosis is essentially a phenomenon of agglutination of blood platelets, the fibrin playing only an insignificant part. If one wishes to know why thrombosis takes place, it is necessary to study the question of agglutination of platelets. If one admits the influence of the blood in the portal circulation on that in the vena cava as Havlicek claims, it is necessary to prove that the portal blood can precipitate the platelets in the other system. All that is known at present is that coagulation never occurs in blood vessels during life unless there has been a precedent thrombosis, even when there is slowing up or complete arrest of the circulation. When the circulation is artificially slowed up, the leukocytes first and later the platelets are seen along the periphery, but there is never agglutination of the platelets. There is a sudden marked increase of platelets during the first few days after operation, returning to normal toward the end of the second week. Now, in certain patients the increase in the number of platelets after operation is exceptionally high and does not recede at the usual time. Whether this can explain some cases of postoperative thrombosis is not proved, but it opens up a field for study. Even if that were proved, it would still be necessary to determine why certain operations stimulate excessive platelet production. Clinical observations show that thrombosis occurs as a rule after operations, especially abdominal, in an aseptic field. During the World War, thrombosis was practically never observed in infected wounds, whereas thrombosis appears like a bolt of lightning from a clear sky after clean appendicitis, hernia and uterine fibroid operations; hence infection cannot be considered as the cause of thrombosis in such cases. Rough handling of muscle tissue certainly favors postoperative thrombosis, yet it seems paradoxical that one never sees a phlebitis following the radical operation for cancer of the breast. One observes thrombosis less frequently in cases in which drainage has been employed than when the operative incision has been closed completely. Leriche is of the opinion that operations performed under ultraviolet or infra-red rays as suggested by Paschoud may lessen the frequency of postoperative thrombosis. Following a visit to the clinic of Paschoud, operations at the Strasbourg University clinic, of which Leriche is the head, are now being performed under these conditions and the use of the infra-red rays during operation has been satisfactory.

"I can appreciate your not desiring to give out the formula of Jergens Lotion or its method of manufacture, but a great many manufacturers of toilet preparations have felt no hesitancy in giving us the names of the ingredients in their products.

"The reason for our original inquiry was that we had received a letter from a dermatologist of Seattle, Wash., who stated: 'I have a patient with a contact eczema resulting from Jergens Lotion, "patch test" positive. Can you tell me the ingredients, also percentage of glycerine et al. contained in it?'

"We regret that you were unable to be of assistance to us in this matter."

In reply to this, the Andrew Jergens Company wrote the following letter to the Bureau of Investigation under date of Nov. 4, 1936, regretting their inability to be of assistance, but

## CUPID FROZE at the touch of her Chapped, Rough Hands!

but a few days later he melted

**Jergens Lotion**

All four sizes—\$1.00, 50¢, 25¢, 10¢—  
contain more lotion than similar sizes of  
other well-known lotions. You'll find the  
big dollar size the most economical of all.  
December 1936 Good Housekeeping

ONLY soft, appealing hands can light the flame of love. But how can you keep your hands exquisite?

Easily enough with Jergens Lotion! Even though the mercury drops. Even though you wash your hands 8 times a day and have them in water at least 8 times more, as any busy woman does!

For Jergens penetrates the deeper skin cells, over-coming their dryness. Compared with other leading lotions tested, Jergens goes into the skin faster, more thoroughly. Its two special softening ingredients make rough, red hands quickly smooth and white again!

Use Jergens whenever your hands have been in water, always after exposure to cold. Then your hands will have the tender softness that brings love!

### FREE! GENEROUS SAMPLE

Prove for yourself how swiftly and thoroughly Jergens goes into the skin, conserves and renews the youth guarding oils and softens your hands again!

PRINT NAME

Address \_\_\_\_\_

still assuring us of their desire to cooperate. Students of English composition will no doubt be interested in the use of the double negative. Or is it the triple negative?

"Considering that many millions of bottles of Jergens Lotion are used annually with no unfavorable reactions coming to our attention, it appears that Jergens Lotion is as nearly 'non-allergic' as anything can be and, also, it seems that few people in many millions are otherwise hypersensitive to its constituents.

"I regret, also, that we were unable to be of greater assistance to you in this particular instance. We are always glad, however, to cooperate to the fullest extent with the American Medical Association, physicians or other consumers."

Being thoroughly convinced by the last Jergens letter that the company's idea of cooperation, as compared to that held by the Bureau of Investigation, was like Kipling's "East is East and West is West," we gave up writing and purchased two original bottles of Jergens Lotion and submitted them to

the A. M. A. Chemical Laboratory for examination. The Laboratory reported:

"Two original bottles of Jergens Lotion (The Andrew Jergens Company) were submitted to the A. M. A. Chemical Laboratory by the Bureau of Investigation for examination.

"The bottles contained 190 cc. (approximately 6½ fluidounces) of a white, viscous, perfumed liquid. The mixture possessed an odor indicative of almond. The reaction toward litmus was found to be alkaline.

"No information concerning the composition of Jergens Lotion appeared on the label, except the following declaration:

"Alcohol 11%"

"Qualitative tests indicated the presence of glycerin, borates, salicylates, water and substance precipitable by alcohol, suggestive of tragacanth.

"From the foregoing tests, it was deemed not advisable to perform further work on the product. The Laboratory concluded that Jergens Lotion is essentially a white, perfumed, hydro-alcoholic preparation containing a mucilaginous substance such as tragacanth, glycerin, boric acid and salicylic acids."

It is hoped that the unfortunate sufferer with eczema recovered during the time consumed by the Jergens correspondence.

When we wrote our first letter, we were naive enough to believe that Mr. Ben Grauer would send the formula of Jergens Lotion forthwith. Those trained radio voices are so sincere. But we received no word from Mr. Grauer, no flash from Walter Winchell or even a tender from Dr. Adams of "Lotions of Love." Maybe we are just too inquisitive.

## Correspondence

### THAT GARLIC ODOR

To the Editor:—We have followed with considerable interest the articles and correspondence on garlic breath odors that have appeared in THE JOURNAL in recent months (Haggard, H. W., and Greenberg, L. A.: Breath Odors from Alliaceous Substances: Cause and Remedy, THE JOURNAL, June 15, 1935, p. 2160. Blankenhorn, M. A., and Richards, C. E.: Garlic Breath Odor, Aug. 8, 1936, p. 409. Haggard, H. W.: Eliminating Odor of Garlic, Sept. 12, 1936, p. 895. Blankenhorn, M. A.: Garlic Odor to Breath, Oct. 17, 1936, p. 1321). No one can seriously doubt that a considerable part of "garlic breath" may be due to retention in the mouth of tiny particles of garlic-tainted foods. Furthermore, as a result of experiments to be mentioned, we can confirm Haggard and Greenberg's experience that chloramine will deodorize these mouth particles. It seems to us that the crucial question to be answered is "When garlic is orally ingested in the customary manner, does a sufficient amount of its volatile oils accumulate in the blood to cause fouling of the breath?" Three different lines of experimentation have led us to the same answer to this question. These experiments comprised (1) the ingestion of garlic in double gelatin capsules, with observation of the appearance time and intensity of garlic odor on the breath, (2) the repetition of the foregoing supplemented by mouth cleansing, shown to be adequate after chewing of garlic, and (3) testing the breath of new-born babies whose mothers had received capsules of garlic during labor.

1. In twelve experiments on ten normal adults, garlic was ingested in gelatin capsules in doses of from 0.5 to 1.5 Gm. The capsules were freshly filled with slightly bruised kernels of raw garlic and were then enclosed in a second capsule so that no odor permeated to the outside. At least two observers, often more, noted the breath of each subject before and during the experiment. It seems superfluous to caution that a subject who has taken garlic cannot detect the garlic breath of others and therefore cannot serve as an observer. The dosage used was chosen because such amounts are frequently ingested in the dietary of certain large groups of our population and was that employed in comparable experiments by Haggard and Greenberg. The sense of smell alone was used to detect the presence of garlic odor. This extremely sensitive method is obviously adequate for the purpose of answering our proposed

Hans-Wilhelm Bansi, one of Gohrhardt's co-workers, discussed the limitations of internal therapy in hyperthyreosis. Operative treatment is indicated if any of the following conditions are presented: paroxysmal tachycardia or absolute arrhythmia traceable to a cardiac lesion (but not an ordinary cardiac acceleration), cardiac dilatation, a hepatic lesion, compression of the trachea, manifest exophthalmos, incipient coma of exophthalmic goiter often appearing in the guise of myasthenia, and finally if the disorder has been present and has advanced for a period of from one year to one and a half years. Slightly increased basal metabolism is a contraindication of surgical treatment.

Ferdinand Sauerbruch contributed some important observations on this topic. He feels that severe exophthalmic goiter is virtually always attributable to a psychic trauma, and especially to a sexual complex in the widest application of the term, to childlessness, for example. In some cases the etiologic factors are to be sought in the domain of the endocrines. Psychogenic cases should receive psychic and climatic treatment, but at the same time an indication for operation, a cardiac lesion, for example, should not be overlooked. Sauerbruch, like other clinicians, has wholly dispensed with radiotherapy; he found that it was rarely of material help and that its use rendered a subsequent intervention more hazardous. Operation should always be radical and only a small portion of the thyroid allowed to remain. Thyroidectomy must still be considered a major operation. Thyroxine has been recommended as a postoperative adjuvant.

Brief mention remains to be made of a session at which the question of virus was discussed. Kurt Herzberg, Düsseldorf hygienist, spoke of the great progress that has been made by the use of the most finely porous filters and by the further development of the types of virus cultures which are found only in living cells. It has also been possible to stain these agents and to visualize their propagation within the cells and even to measure their size (from 10 to 175 microns). Whether the virus should be considered a living substance is debatable, yet its ability to divide, for example, suggests an affirmative supposition. According to Otto Waldmann of Insel Riems, progress has also been made in the study of influenza and specifically in the discovery of a transmissible virus that, together with the influenza bacillus of Pfeiffer, produces influenza in man. It has been possible to cultivate this virus in vitro.

### Duodenitis and Splenomegaly

Professor Greppi in a lecture before the Accademia Medica of Rome spoke on several cases of suppuration of the spleen and sometimes also of the liver, complicated by duodenitis. The speaker discussed the significance of the association of gastro-duodenal and splenic diseases. Professor Frugoni of Rome asked if the liver is not of the same or of more importance than the spleen in the origin of duodenal disease. He said that in the majority of cases of hemorrhage, associated with chronic splenomegaly, the anatomic examination and the clinical symptoms (violent vomiting of blood) seem to point out that the hemorrhages are of esophageal and gastric origin rather than of duodenal.

Professor Matronola said that the roentgen examination of a patient showed the presence of a duodenal niche. In this case the presence of duodenal ulcer was suspected and the patient had intestinal hemorrhage. During operation no ulcer was found. The spleen was in a pathologic condition, and it was removed. The anatomic diagnosis could not be made by the histologic examination of the spleen and of a large ganglion,

which was removed during the operation. At present, the patient is suffering from slight jaundice, and he is under observation.

Professor Greppi said that he did not consider the association of the mentioned diseases as a new syndrome. He called attention to the fact that duodenal and pyloric disturbances frequently complicate splenomegaly and hepatomegaly in the same manner in which esophagocardial circulatory alterations occur. Duodenal and pyloric complications are associated with dyspepsia, gastric disturbances and hemorrhages. They originate on a congestive phlogosis of the mucosa and may simulate duodenal ulcer.

### Gastric Ulcer of the Lesser Curvature

Professor Durante of Genoa gave a review of a large number of cases of ulcer of the lesser curvature treated by surgery in the Ospedali Civili of that city. The operation of selection is gastric resection followed by reconstruction. There are, however, certain patients who cannot stand this type of operation because of poor general conditions. In these cases performing of a simple section of the vascular arcade of the juxta-ulcerous curve, a wedged resection with or without gastro-enterostomy or a longitudinal resection is indicated. The speaker made a comparative study of the results of wedged and longitudinal resection. He found that the results of resection in a saddle form, without gastro-enterostomy, are unsatisfactory. Frequently they are complicated by stenosis because of the proximity of the pylorus to the cardia or by the slight elevation of the pyloro-antral segment with consequent gastric dilatation and diminution of motility. In some cases the ulcer recurs at the segments near the point at which resection was made.

### Society Reunion

The Società Medico-Chirurgica of Pavia met in that city under the chairmanship of Professor Pensa. Professor Sala spoke on the collection of unpublished letters of Antonio Scarpa, the anatomist. He presented a motion on publishing Scarpa's letters in celebration of the fiftieth anniversary of the foundation of the society.

Dr. Pellegrini discussed the behavior of the cardiac output during experimentally induced fever. When the latter is high a condition of cardiovascular insufficiency appears which is analogous to vascular collapse rather than to cardiac hypodynamia. This behavior of the cardiac output is frequent although it may be lacking in some cases.

Drs. Ferrari and Bertola discussed some of the organic modifications induced by pneumoperitoneum. When small amounts of air are injected by the common technic, the modifications of circulation and respiration are slight and transient, the pulse rate diminishes, arterial pressure frequently diminishes and venous pressure does not change. Some of the organic changes that follow pneumoperitoneum can be included within the picture of transient and incomplete shock. The speakers reported, also, results of studies on the concentration of proteins in the blood serum and the velocity of sedimentation of erythrocytes. The former diminishes and the latter increases after performance of pneumoperitoneum. The changes of the proteins in the blood and of the velocity of sedimentation of the erythrocytes may be considered within a picture of hemoclastic crisis.

### Congress of the Medical Press

The Fourth International Congress of the Medical Press was held in Venice, presided over by Dr. Davide Giordano, a senator. The minister of national education was present. The first official topic discussed was "History of the Medical Press in Latin Countries." Official speakers on this topic were the delegates from Belgium, France, Spain and Switzerland. Professor Pazzini, the Italian delegate, described

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### DEATH FROM HYPERTHERMIA IN HEAT TREATMENT OF SYPHILIS

To the Editor:—For approximately six years I have had as a patient a man suffering from syphilis. When he first consulted me he had secondary manifestations and a four plus Wassermann reaction. He was given nearsphenamine, intramuscular bismuth and mercury. A course of treatment consisted of twelve to fifteen weeks and then a rest period varying from four to six weeks, when a blood test was made to determine the progress. In December 1933 his blood Wassermann reaction was negative. At this time a spinal puncture was made and this was negative. I informed my patient that he was cured of syphilis so far as medical science was able to determine but advised blood tests every six months for the next three years. Later the patient moved to the east coast. He consulted me again in 1935 and stated that he had had no blood tests made while away. Wassermann, Kolmer and Kahn blood tests made at this time were all reported four plus. Not being satisfied with the report of one laboratory, I sent his blood to another. This report was the same. There was no history of new infection. Treatment was again instituted, it being the same as the earlier courses except that after a time I changed to marpharsen, giving him 0.06 Gm. once every week along with sodium iodide. But I was never again able to obtain a negative Wassermann reaction. A few months ago I called to this patient's attention the reports appearing in THE JOURNAL regarding the good results obtained by hyperpyrexia and had him read a few of these articles. We decided on this therapeutic measure. The patient's height was 5 feet 7 inches (170 cm.), weight 154 pounds (70 Kg.) and age 49 years. As far as I was able to determine he was in perfect physical condition. The blood pressure was normal. The urine was normal. There were no cardiac murmurs. The lungs were normal. There were no masses or tenderness in the abdomen. The reflexes were all normal. In other words, my impression was that I was dealing with a man in perfect health, his only disability being the reaction of the blood. He was particularly insistent that he obtain a negative Wassermann reaction if possible. Nov. 29, 1936, I had him report to a physical therapy technician who has given more than 500 hyperpyrexia treatments and has treated other patients of mine with excellent results. The method of application was through the electric blanket. The time, temperature by mouth and pulse were as follows:

Time	Temperature	Pulse
9:10 a. m.....	97 F.	80
9:42 a. m.....	98.4 F.	98
10:05 a. m.....	100.6 F.	108
10:20 a. m.....	102 F.	120
10:40 a. m.....	104 F.	138
10:45 a. m.....	104.4 F.	140
11:10 a. m.....	106 F.	104

At this time I gave the patient morphine sulfate one-fourth grain (0.016 Gm.) hypodermically, with instructions to hold the temperature at that level for three hours and then permit a gradual cooling off in the afternoon.

Time	Temperature	Pulse
11:45 a. m.....	106 F.	130
12:10 p. m.....	106 F.	132
1:00 p. m.....	106 F.	140

At that time the current was turned off, the blanket loosened and the patient permitted to cool slightly. At 2 o'clock his temperature was 105.8 and pulse 120. In the early afternoon I was called to a nearby city to see a patient suffering from angina pectoris. On my return I found that the patient had died at 2:55 p. m. At 2:20 his heart first showed evidence of weakness. Efforts were made to cool him rapidly. Stimulation was applied as much as a technician could apply. The postmortem was performed by the coroner on my refusal to sign the death certificate. The examination showed the brain, spleen, liver and kidneys to be normal, although the coroner did think that there was some evidence of myocardial weakness. The lungs showed passive congestion of the right lower lobe. Autopsy was performed by a surgeon of vast experience and his conclusions were that death was due to hyperpyrexia due to hypersusceptibility to heat being used in treating syphilis. Please omit name.

M.D., California.

ANSWER.—This case presents a complicated problem which does not lend itself to ready solution from the evidence presented. The patient appeared to be an excellent risk despite his age of 49 years, and the treatment seems to have been uneventful until 2 p. m. A satisfactory fever was produced within a reasonable time and was maintained at a constant level. The pulse rate as recorded was never alarming. In the absence of an excessive pulse rate the evidence of cardiac weakness is puzzling. Cyanosis, dyspnea or a poor volume pulse would have been preceded or accompanied by an increased pulse rate. At any event, something unusual was observed at 2:20 p. m. A satisfactory explanation of developments from this time until death supervened at 2:55 is impossible without further knowledge of details.

A temperature of 106 F. by mouth is equivalent to 106.8 or 106.8 by rectum. At such temperatures a moderate amount of physical exertion may cause a rapid elevation of fever. When the heart first showed evidence of weakness, the patient probably developed restlessness, mania or even convulsions, with a substantial increase in heat production due to muscular work and a rapid rise in body temperature. Efforts made to cool such a patient rapidly by applying cold to the skin produce marked vasoconstriction, effectively preventing heat radiation. What happened in this case is unknown, but the following sequence of events has been observed three times and may be analogous to the case under discussion: During the course of a fever treatment at 107 F. which had been well tolerated up to this time, the patient suddenly became restless and uneasy and the temperature began to rise. In ten or fifteen minutes the patient became disoriented and maniacal and soon lapsed into deep coma. While efforts at resuscitation were being made the respirations became shallow and infrequent, the blood pressure fell to a very low level, even to zero, and the peripheral pulse became imperceptible. The skin was hot and cyanotic and the rectal temperature rose to over 109 F. Precordial activity was increased and the heart was very rapid with a rate of 180 to 200 per minute, but the heart sounds were of good quality. Except for the fever and the hot and cyanotic skin, the condition strongly suggested profound surgical shock. With the prompt administration of epinephrine and caffeine with sodium benzoate and the injection of 100 cc. of 50 per cent dextrose solution intravenously the pulse volume improved, the blood pressure rose very promptly, and the patient came out of coma in a few minutes. If this condition simulating surgical shock was to persist for a short while, even from fifteen to thirty minutes, death from anoxemia probably would result.

In the case under discussion, undue restlessness may have resulted from impending tetany. Hyperventilation during fever therapy occurs as the result of stimulation of the respiratory center from direct heating of the skin. This may produce tetany because of the profound depression of the carbon dioxide content of the blood. Hyperventilation probably was not a factor here because of the morphine effect in depressing respiration. The loss of chlorides through the sweat may result in the production of alkalosis and tetany. It has been established that about 20 Gm. of sodium chloride is excreted through the skin during a five hour fever treatment. No mention is made of the fluid or chloride intake during the treatment.

It seems evident that death in this case was due to hyperpyrexia. The diagnosis of hypersusceptibility to heat, however, seems unreasonable. This patient was able to tolerate a very high body temperature for several hours. It seems likely that he died only after his body temperature reached an extremely high level, a level which frequently causes death in cases of heat prostration. Death probably resulted from anoxemia due to circulatory and respiratory collapse. A satisfactory pathologic diagnosis in such cases often cannot be made. Death occurs so rapidly that organic changes are scarcely to be expected and even passive hyperemia may be slight or absent. Because of the circulatory collapse, petechial hemorrhages are not produced.

### CLIMATIC CHANGE AFTER PNEUMONIA

To the Editor:—A youth, aged 17, had an attack of lobar pneumonia in December 1935, which was aborted by the use of bivalent antipneumococcus serum. Recovery was rapid, but three months later lobar pneumonia again developed. Because of a severe reaction during the administering of serum, this manner of treatment was not continued. A rather typical course ensued with the temperature returning to normal about the ninth day by lysis. The temperature remained normal five days, when he began to have severe pain in the right lower part of the chest anteriorly about the same site in which the process began. He raised bloody sputum and the temperature was above normal for about five days. The highest point it reached during this attack was 101 F. I thought this was a relapse. The chest signs have all cleared up and he seems to be in excellent condition. His family, which is in only moderate circumstances, has asked as to whether or not a change to a warmer and more equable climate would be advisable for the winter months. Such a change would be quite an economic strain. Please omit name.

M.D., West Virginia.

ANSWER.—Lobar pneumonia as a rule clears up completely or it leaves rather obvious complications. The question does not state the location of the first attack, but one wonders whether the entire process was not a continuation of the original infection.

It is true that some persons are much more susceptible to pneumococcal infection than are others, so information regarding previous attacks of pneumonia would have a bearing on this case.

Violent deaths accounted for 3 per cent of the total; by far the largest number of such fatalities were due to traffic accidents involving automobiles.

### The Antituberculosis Campaign

Included in the annual report of the Antituberculosis Society of Amsterdam is a résumé by Mr. Heynsius Van Den Berg of the society's activities during 1935.

The results have been gratifying. The mortality from all forms of tuberculosis has declined from 4.88 to 4.34 per 10,000 of population and the mortality from pulmonary tuberculosis has declined from 3.54 to 3.4.

In 1918 the corresponding figures were still 22.65 and 18.03, respectively.

The present figures for Amsterdam (5.25 and 3.75) are among the lowest in the world and are still below the rate for the entire kingdom.

An extended examination was made in the course of the same year (1935) in order to ascertain the earliest stage of life at which tuberculosis may be detected. The subjects were infants and young children aged from 0 to 4 years. Establishment of a tuberculous condition was possible in 50.8 per cent of the children.

Miss Ruys has been able to determine at Amsterdam that in 12.9 per cent of tuberculosis cases among children, infection from bovine bacilli has taken place.

### BUENOS AIRES

(From Our Regular Correspondent)

Nov. 1, 1936.

#### Action of Acetylcholine

Prof. A. Lanari, in a lecture before the Sociedad Argentina de Biología, reported on the reactions of the muscles of the forearm and the hand following the injection of 0.04 Gm. of acetylcholine in the humeral artery at the level of the fold of the elbow. In muscles with the electrical reaction of degeneration, a contracture that lasts for half a minute takes place. In hemiplegic pyramidal contracture the contracture in flexion is exaggerated. In extrapyramidal rigidity there is either no contracture or only a slight flexure of the hand and the fingers. In myotonic myopathy a local intense contracture is obtained. In normal persons and in progressive muscular dystrophy no contracture takes place. In normal persons and in persons who recently have had sympathectomy performed, local pain, rubor, perspiration and increase of the arterial oscillations take place. In some persons who have had sympathectomy performed several months before administration of acetylcholine injection, pain and slight rubor persist, perspiration is lacking and the arterial oscillations diminish (which shows vasoconstriction of the arteries and arterioles).

#### Hospital Physicians To Be Paid

The campaign carried on by more than 2,000 physicians of Buenos Aires who up to the present have given their services to the public in the hospitals of the city without any remuneration has succeeded. A bill has been approved by the national congress by which an allowance of 5,000,000 pesos (about \$2,500,000) will be given every year from now on to pay physicians in public hospitals for the work they do.

#### Society News

The first Argentinian Congress of Ophthalmology, which was organized by the Sociedad Argentina de Oftalmología and presided over by Dr. Damel, took place recently in Buenos Aires. Ophthalmologists from Brazil, Uruguay and Bolivia were present at the congress.

The second Medico Gremial Argentinian Congress took place in Buenos Aires, October 30. The following topics were dis-

cussed: economic distress of physicians, biologic conditions of the average population (food, salary, housing and work), unification and coordination of medical services, societies of mutual insurance and of medical cooperation, social work and medical studies. The problems that originate in the plethora of physicians and in the interference of the state in controlling the administration of medical services were discussed. The meetings lasted longer than was expected because of the many articles presented and the breaking in of speakers with political or social views into the discussions.

The eighth Argentinian Congress of Surgery took place in Buenos Aires, October 4. Dr. Alejandro Ceballos was the chairman. An exposition with surgical instruments, items of pathologic anatomy and roentgenograms in connection with the subjects discussed was opened. The topics discussed were renal lithiasis, tuberculosis of female genital organs and cancer of the rectum.

#### Personals

Professors Castex, Houssay, Arce and Martínez have been appointed members of the Academia Rumana of Medicine.

Prof. B. A. Houssay has been given the degree of Doctor honoris causa by Harvard University. Dr. Houssay was invited to Cambridge to participate in the celebration of the three hundredth anniversary of the university. He has also been given the degree of Doctor honoris causa by the University of São Paulo and named one of the seventy members of the new group Pontificia Academia Scientiarum of Rome.

The national prizes of medical sciences of 1931 and 1934 were awarded as follows: The first prize, 20,000 pesos (about \$10,000) to Prof. Pedro Belou for his studies of the arterial system. The second prize of 12,000 pesos (about \$6,000) was given to Prof. Enrique Hug of Rosario for his studies on hydrocyanic poisoning and its treatment. The third prize of 8,000 pesos (about \$4,000) was given to Dr. O. Ivanisovich for his work on hydatidosis of the bones.

Drs. Mario Soto, Osvaldo Loudet and Marcelino Sepich were appointed professors of pharmacology and therapeutics, psychiatry and neurology, respectively, at the new faculty of medicine of La Plata.

#### Deaths

Dr. Juan Carlos Navarro, ex-president of the National Academy of Medicine and extraordinary professor of pediatrics, is dead.

Dr. José Borda, ex-professor of psychiatry and former director of the Hospicio de las Mercedes and member of the National Academy of Medicine, is dead.

## Marriages

JAMES HAROLD MACART, East Orange, N. J., to Miss Beatrice Elsa Birkenhauer of Maplewood, in Newark, Sept. 12, 1936.

ALMER RUSSELL AANES, Red Wing, Minn., to Miss Irene Lucille Persgard of Duluth, in Minneapolis, Sept. 26, 1936.

SAMUEL M. BEALE JR., Sandwich, Ont., Canada, to Miss Mabelle H. Slayton in New York, Oct. 2, 1936.

JOHN RAYMOND MALLOY, Brattleboro, Vt., to Miss Bernice Harriet O'Neal of Waterbury, Conn., recently.

RUSSELL EVAN MORGAN, Annville, Pa., to Miss Elizabeth Johanna Wenzinger of Philadelphia, recently.

EDWARD LEE GILBERT to Miss Ernestine Flynt, both of Winston-Salem, N. C., in October 1936.

LEWIS W. GLATZAU to Mrs. Winnifred McDonald, both of Daytona Beach, Fla., Nov. 12, 1936.

RUDOLPH FARMER, State Park, S. C., to Miss Bernice Turner in Columbia, Sept. 25, 1936.

JAMES FORTIN MINNES to Miss Margaret Whitehead, both of Baltimore, Oct. 3, 1936.

it is better to avoid the use of milk of this type. As this is not always possible, such milk should be boiled before being used in the feeding mixture. In most instances, the changes are in all probability physical, for in the freezing of the water the emulsion breaks and the fat becomes separated. When the milk is thawed, the fat globules coalesce and form a thick layer of butter fat which may cause a gastric and intestinal upset. Milk that has been frozen is less likely to show changes in the fat emulsion if the process of thawing goes on slowly in a cool room. Pennington and her collaborators also found that changes occurred in the protein of milk that was held for a considerable period at a temperature of 0 C. These changes resulted in proteolysis of the casein and of the lactalbumin."

#### IRRITATION FROM BENZEDRINE INHALER

*To the Editor:*—A man, aged 26, during the course of half an hour, took twelve large sniffs from a benzedrine inhaler, in spite of the warning not to overdose. The usual clearing of the nasal passages occurred. One hour later, on going out into the open air, he was suddenly seized with an attack of violent sneezing, a burning, stinging, itching and sharp intermittent lancinating pain, which passed through his nose and up into the frontal region, together with severe lacrimation and a profuse seromucous discharge from the nasal passages. The sneezing was relieved by mouth breathing but the other symptoms persisted. There was no feeling of anxiety and no other symptoms were noted. The patient had just recovered from a severe cold and sinusitis of about ten days' duration, during which time he had used the benzedrine inhaler according to directions. He had not used the inhaler for about four days prior to the present episode. Examination revealed a markedly injected conjunctiva, hyperemic nasal mucosa and much swollen turbinates. There was profuse lacrimal and nasal secretion. The temperature was 98.6 F., pulse 108, respiration 18. The blood pressure was not taken but as estimated by palpation was slightly elevated. Physical examination was not remarkable otherwise. Smears revealed the absence of eosinophils. One and one-half hours after the onset, the patient was given atropine  $\frac{1}{120}$  grain (0.5 mg.) for relief of profuse secretion, and liquid petrolatum was dropped into the nose. The atropine only served to increase the discomfort by adding to the dryness when the patient breathed through his mouth. The liquid petrolatum had no effect. Three hours after the onset the nasal mucosa was sprayed with epinephrine and 0.5 per cent cocaine solution. These failed to shrink the turbinates and the hyperemia persisted, but the anesthetic properties of the cocaine relieved the distressing symptoms for about forty-five minutes. Epinephrine 1:1,000 hypodermically had no effect in relieving the symptoms. The burning, itching, stinging, lancinating pain, lacrimation and hyperemia have persisted for forty-eight hours but have decreased slightly in severity. No relief has been obtained except through the use of 0.5 per cent cocaine. Consultation of the literature in the local medical library has revealed nothing in the way of therapy. Can you offer any suggestions as to therapy in future cases of this sort? Is it logical to assume that the overdose of benzedrine was responsible for the symptoms and what was the nature of the action? Could it be that the menthol in the inhaler was responsible? Is benzedrine habit forming? Thank you for any information you may offer.

M.D., Ohio.

*ANSWER:*—The symptoms described are obviously due to irritation, which might have been caused by the rather excessive use of the inhalant or might have been due indirectly to the medicament but directly to the extension of inflammation that was present. A soothing mucous membrane ointment containing tragacanth or even cold cream, possibly with the addition of a small amount of cocaine, might give the greatest degree of relief. Benzedrine is not habit forming in the sense a narcotic is; but, of course, it is merely a symptomatic remedy and does not cure the disturbance.

#### USE OF ELECTROCARDIOGRAPH IN DETERMINING AURICULAR AND VENTRICULAR RATES

*To the Editor:*—Please state methods for determination of auricular and ventricular rates from electrocardiographic tracings. Please omit name.

M.D., West Virginia.

*ANSWER:*—The modern electrocardiograph is equipped with a standard timer which produces vertical lines at intervals of 0.04 second. Every fifth vertical line is registered heavier and marks intervals of 0.2 second. Some electrocardiographs with motors run by clockwork have omitted the time lines, the time being obtained by inserting the record under a transparent scale which the manufacturers have provided. There are two common methods used to estimate the heart rate. The first is to determine the time interval for a number of beats between homologous points on the QRS complexes, in the case of ventricular rate, and on the P waves for auricular rate, and from these compute the average. The heart rate can then be determined by dividing sixty seconds by the duration of the average cycle. The second method is to determine the number of beats occurring in five, ten or fifteen seconds and then multiplying by 12, 6 or 4 respectively; in this way the average rate may be obtained. Rulers have recently been marketed by which

the latter method is facilitated, but these rulers require that the camera speed be at a fixed and uniform rate. When the auricles are fibrillating the calculation of the fibrillating rate is more difficult, but approximations may be obtained in the leads in which the fibrillating waves are clearly discernible. When the rhythm is disturbed by ectopic beats, it is customary to ignore these beats and determine only the rate of the predominant rhythm.

#### CRYING OF FETUS IN UTERO

*To the Editor:*—On the morning of Sept. 30, 1936, I had an obstetric call to a patient who had had no antepartum care, was anemic, and had the appearance of having uremic poison. Eighteen hours prior to this she had had an opiate. On making a vaginal examination, I found a breech presentation in the cervix dilated about 2 inches in diameter. While I was examining the patient, the amniotic sac ruptured. I waited two hours and no progress had been made. The patient being too weak to deliver, I decided to try forceps. Just as I had everything ready and the nurse started to give the anesthetic, the baby began crying; it could be heard all over the room and by an uncle in the adjoining room. We postponed giving the anesthetic, because it was such an unusual occurrence. It cried for three minutes and then there was a pause for about two minutes; then it started crying again, this time for about two and a half minutes. At this time the cervix had not dilated any more than at my previous examination two hours prior. There was no part of the baby's body out of the uterus and I questioned whether I was going to be able to deliver her at this time without considerable difficulty on account of the cervix not being dilated any more than it was. I delivered the baby and it weighed  $6\frac{1}{2}$  pounds (2.9 Kg.). It was a normal healthy baby and the mother recuperated nicely. I have never heard of a case like this before and wondered whether any one else had ever had the same experience. The father stated that the baby had cried three months before, but there is no proof of this. I know that the baby cried in the uterus during delivery and have three people who will sign affidavits to this effect.

J. H. CORBETT, M.D., Jasper, Fla.

*ANSWER:*—There are many cases of crying by the fetus in utero. Vagitus uterinus is the term for it. When air gains access to the uterus (as it did in this case during the time the examination was made) the baby may inspire some and emit cries. Usually the babies are dyspneic and therefore breathe, but cases are on record in which the baby was well (as in the case reported) and was delivered even several days after the crying episode.

Kristeller reported a case in which the child cried each time the forceps was closed on its head, eight times in all. It is said that Mahomet and St. Bartholomew cried while in the uterus. Unless the child shows signs of distress, the case should be left to nature. The subject has been discussed by von Klein (*Monatschr. f. Geburtsh. u. Gynäk.* 60:154 [Oct.] 1922).

#### COMPOUND SPIRIT OF HORSERADISH

*To the Editor:*—Several years ago I used to write a prescription containing compound spirit of horseradish made from the dried root, but now it seems the druggists can't get this made from the dried root. Do you know where I might procure this, because I can't possibly use the fresh root spirits? The druggist who filled this prescription is dead, and I have no idea where he got the dried root. If you can give me this information I will very much appreciate it.

FRANKLIN H. BROYLES, M.D., Bethany, Mo.

*ANSWER:*—The compound spirit of horseradish, spiritus armoraciacae compositus, is made, according to the British Pharmacopoeia, from

Horseradish root, scraped.....	125 Gm.
Dried bitter orange, well bruised.....	125 Gm.
Nutmeg, bruised .....	31.5 Gm.
Alcohol .....	625 cc.
Distilled water .....	750 cc.

This mixture is subjected to distillation until 1,000 cc. is secured. It is obvious that it is the fresh and not the dried root that is desirable, because the latter would have but little of the volatile products. If, however, the spirit made from the dried root is desired, it is barely possible that the dried root might be secured from some dealers; but, if not, there is no reason why horseradish root might not be dried before being used.

#### TETANUS ANTITOXIN AND TOXOID

*To the Editor:*—Please advise me how long continued the effect of tetanus antitoxin is and how frequently it may be administered in cases warranting its use on account of receipt of new injuries, as a prophylactic measure. The standard textbook on medicine and therapeutics in which I have referred makes no mention of the duration of the passive immunity conferred by use of this agent.

FRED M. DULA, M.D., Lenoir, N. C.

*ANSWER:*—The passive immunity conferred by tetanus antitoxin lasts for a period up to six weeks but should not be depended on for more than two weeks. For the production of more permanent protection, tetanus toxoid should be employed.

during the World War; aged 69; died, Nov. 15, 1936, in the Harper Hospital, Detroit, of carcinoma of the bladder.

**James Francis Lawson**, Chicago; Howard University College of Medicine, Washington, D. C., 1907; served during the World War; member of the city board of health; aged 51; died, Nov. 3, 1936, in the Veterans Administration Facility, Hines, Ill., of hypertension and valvular heart disease.

**Clarence E. Axline**, Peoria, Ill.; Louisville (Ky.) Medical College, 1881; aged 80; died, Nov. 1, 1936, of arteriosclerosis and myocarditis.

#### CORRECTION

The information in THE JOURNAL, Dec. 5, 1936, page 1908, that Dr. William Edgar Hover of Sarasota, Fla., was a graduate of the Medical School of Maine, Portland, 1888, was incorrect. It should have been Medical College of Ohio, Cincinnati, 1888.

## Bureau of Investigation

### JERGENS LOTION

#### A Lesson in the Art of Correspondence

The Andrew Jergens Company, makers of "Jergens Lotion" and radio sponsor for gossip Walter Winchell, just will not say what is in it, even to help out a lady who seems sensitive.

The Bureau of Investigation received from a dermatologist a letter which read:

"I have a patient with contact eczema resulting from Jergens Lotion, 'patch test' positive. Can you tell me the ingredients, also percentage of glycerine et al. contained in it?"

The Bureau maintains files regarding all sorts of proprietary preparations. The first item in the Jergens collection was a 1914 soap wrapper bearing a reproduction of the "neckless head" of John H. Woodbury, with the word "Dermatologist" beneath his signature. Attached was a 1903 advertisement of the John H. Woodbury Dermatological Institute of New York City, promising permanent and safe removal of "freckles, tan, moth blotches, liver spots, moles, warts, tattoo, powder or birth marks, superfluous hair, scars, wens, cysts, and all disfiguring, humiliating blemishes, on, in or under the skin, without leaving a trace of their former existence."

Next came a clipping from the *Oil, Paint and Drug Reporter* of Oct. 30, 1922, detailing some litigation between the Andrew Jergens Company and William A. Woodbury, Inc., in which it was brought out that in 1901 the Jergens Company acquired from John H. Woodbury and the Woodbury Dermatological Institute the right to make facial soap and toilet preparations, with the right to use the "neckless head" trade-mark.

So a letter was written to the Jergens Company on Oct. 16, 1936, stating, in substance, that our files seemed to contain no data on Jergens Lotion, and that we would appreciate some information on the subject. On October 20 the Jergens Company replied:

"A satisfactory reply to your letter of October 16th is difficult because we have no idea what it is your correspondents wish to know about Jergens Lotion.

"If you can particularize it, we shall be glad to endeavor to supply a suitable answer.

Your truly,

THE ANDREW JERGENS CO.  
(Signed) Robert V. Beucus  
Advertising Manager"

RVBeucus  
EG

The reason for not particularizing in our first letter to the Jergens Company arose from a desire to spare the feelings of Mr. Ben Grauer, commercial announcer on the Walter Winchell-Jergens Program. Having frequently listened to that gentleman lamenting the disadvantages of red and chapped hands, we were afraid of the acute mental shock Mr. Grauer would suffer on learning that a case of contact eczema had developed following the use of Jergens Lotion. He sounds just that sincere on the air. However, being forced to "particularize," we wrote:

"I regret that I did not make myself clear in my letter to you of October 16 regarding Jergens Lotion. We should like to have information regarding the ingredients contained in Jergens Lotion. It is not necessary, however, to have the exact amounts."

We then received the following letter, dated October 24, from Philip D. Adams, Ph.D., of the Jergens Company:

"Mr. R. V. Beucus has just placed before me your own and his correspondence of October 16th, 20th and 22nd, relative to the constituents of Jergens Lotion, with the request that I take up the matter for further cooperation with the Bureau of Investigation. For obvious reasons, we do not disclose the composition of Jergens Lotion.

"Having already examined all the known reports on the pharmacologic effects of Jergens Lotion constituents and, with the guidance of our advisory dermatologists, it is very likely we can supply satisfactory information to you on all other specific inquiries.

"In a preliminary way, we can assure you of the following: Jergens Lotion contains no metallic substances, as mercury or lead; it contains no substances to which many people are allergic or hypersensitive, as proteins or their decomposition products; it contains no materials such as hormones or other animal organ extracts.

"If we can in any way cooperate further with the Bureau of Investigation, please write me again concerning your specific inquiries."

Being considerably confused by the Jergens idea of cooperation, we wrote to Dr. Adams on October 27 as follows:

"I appreciate having your letter of October 24, but am sure you realize that it contained no information of value to this Department. Knowing what something does *not* contain is of little use in answering inquiries.

## Book Notices

**Modern Treatment of Diseases of the Respiratory System.** By A. Lisle Punch, M.B., M.R.C.P., Senior Physician, Royal Northern Hospital, and F. A. Knott, M.D., M.R.C.P., D.P.H., Director of Bacteriological Department and Lecturer in Bacteriology to Medical and Dental Schools, Guy's Hospital. Cloth. Price, \$5. Pp. 295, with 127 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

This volume is a practical handbook for the physician. The first eleven chapters are devoted to nontuberculous conditions of the upper respiratory tract, lungs, bronchi and pleura. Although emphasis is placed on the treatment of these conditions, considerable space is given to diagnosis and prevention. The diagnostic and therapeutic values of iodized oil and the methods of administration are fully discussed and the subject is illustrated by roentgenograms of the chest after iodized oil has been introduced. In the chapter on bronchial asthma and hay fever, considerable emphasis is placed on desensitization. The chapter on pneumonia presents the modern methods of treatment, such as serum therapy, administration of oxygen, and blood transfusion. Artificial pneumothorax is given a place for the almost instant relief of pain but is not thought to have any beneficial influence on the pneumonic process itself. A profusely illustrated chapter is devoted to intrathoracic tumors, and the more modern methods of diagnosis are adequately described. The various fungous diseases, asbestosis, silicosis, syphilis and fibrosis of the lung are included in one short chapter. Eighty-eight pages are devoted to chronic, pulmonary tuberculosis, in which diagnostic points are presented and the various methods of treatment described. Tuberculosis among children is described under the term "epituberculosis," which in reality is a part of the primary complex. Attention is called to the fact that this condition "invariably clears up without special treatment." Under the subject of artificial pneumothorax the ambulatory method of treatment, which is rapidly gaining in popularity in this country, is considered of value when it is impossible for the patient to be hospitalized or to remain in bed long at home. A good many workers in the United States will disagree with the statements concerning the length of time artificial pneumothorax should be continued, particularly in advanced cases with large cavities. The authors look on sanatorium treatment as only the first step in the management of the tuberculous patient and call attention to the care that must be provided after discharge from the institution. All the modern surgical procedures employed in the treatment of pulmonary tuberculosis are presented. In discussing the prevention of tuberculosis, the authors make the following statement: "Therefore application of BCG in the prevention of systemic tuberculosis in man is still unattempted in this country. The situation presents most difficult problems, and these are as yet sufficiently far from practical solution to make it unlikely that BCG or any allied preparation will in the immediate future be advocated for use by practitioners in England."

**Begabung im Lichte der Eugenik: Forschungen über Biologie, Psychologie und Soziologie der Begabung.** Von Dr. Josef Somogyi, Hochschulprofessor in Szeged. Paper. Price, 14 marks; 22.68 Austrian schillings. Pp. 518, with 47 illustrations. Leipzig & Vienna: Franz Deuticke, 1936.

Although this is a Hungarian work, it follows the Teutonic pattern of massiveness and thoroughness and treats largely with literature of the subject rather than with original research. The author has made a thorough study into the subject of special talents and, as the title indicates, has approached it from the standpoint of eugenics. The subject of talent is taken up from almost every point of view. The volume begins with a discussion of the genetics of talent, discussing heredity and eugenics with particular regard to psychologic features. The author takes up the matter of talent from the standpoint of body build and associated physical characteristics, laying great

stress on Kretschmar's work, and he interrelates with this part a discussion of talent as found in the various races.

The second of the three main divisions of the book takes up in great detail the matter of psychologic traits such as intelligence, emotional factors and the various degrees of talent, with special reference to genius. There is a discussion of the various means of testing talent and also a discussion of the classification of different types of talented individuals. The point of view of the psychologic part of this volume is rather conventional. There is little included which cannot be found in other works, such as that of Terman, dealing with genius, yet one can find here a thorough analysis of the literature in French, German and English. While it is possible that the American work which has been done on this subject has been somewhat neglected, it cannot be gainsaid that Somogyi has touched on most of the important material. He does not hesitate to cite parallelisms determined on lower animals and he also presents historical and other material which, although related, is not strictly scientific.

The last part of the work deals with the sociological angle of the problem of talent. In his introduction the author stresses the fact that this is a democratic world and that, while all people are given an equal chance to develop, those with talent seem to get further, and it is worth while making a study of what it is that makes these people stand out. Since that is the angle which he takes, one can see that a sociological presentation in which he discusses individual and family relationships, group and race characteristics, and other similar features must be of importance.

Somogyi closes the book with a discussion of his ideas on what should be done about developing talent. He points out the need for the eugenic approach to induce the improvement of inherent characteristics, and also an educational approach for the development of existing talent. He has done an excellent and thorough piece of work, and much material is collected here which cannot be found easily in any other single volume.

**A Textbook of Obstetrics.** By Edward A. Schumann, A.B., M.D., F.A.C.S., Professor of Obstetrics, School of Medicine, University of Pennsylvania. Cloth. Price, \$6.50. Pp. 780, with 581 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

The author has succeeded in writing a book on obstetrics which seems to omit little, if anything, of much practical importance. It is about half the size of the usual textbook of obstetrics. This has been accomplished by leaving out discussions of unproved theories and limiting those on the historical side of obstetrics. Great weight has been given to the mechanics of childbirth and its common complications, but the rarer conditions are only briefly sketched. The book is well illustrated. Among the numerous and fitting illustrations, one recognizes many that have been adapted from other books, but always with the proper credit line. There are chapters on the physiology of the fetus, the physiology of pregnancy, the diagnosis of pregnancy, the anatomy and physiology of labor, and the conduct of labor. In the chapter on analgesia and anesthesia in obstetrics, it is stated that the morphine-scopolamine combination was first advocated by Steinbuechel in 1902 and was much lauded by Gauss in 1906, who coined the happy term "dammerschlaf," or twilight sleep. Unfortunately the lay press took up the subject of relief of pain during labor and exaggerated its successes. The author believes, however, that morphine and scopolamine, with a modification of the original conduct of twilight sleep, gives more uniformly satisfactory results than any other form of analgesic agent of which he has knowledge. He also discusses the Gwathmey method, the use of nitrous oxide and oxygen, the use of the barbiturates, the use of ether, chloroform or ethylene, and spinal anesthesia. There are chapters on the toxemias of pregnancy, abortion, the extra-uterine pregnancy, placenta praevia, anomalies of the birth canal, postpartum hemorrhage, puerperal sepsis, injuries and accidents of the infant, the obstetric forceps, and others.

The maternal mortality during the process of reproduction is said to vary from 0.4 to 0.7 per cent throughout the civilized world; in spite of the improvements in obstetric methods and teaching, these figures have not been lowered appreciably during the past quarter century. Lea has said that advances in sepsis and in surgical technic have been nearly balanced by the increased tendency to unwise operative intervention as the result of the confidence inspired by these advances. The author's object in preparing the book was to present the art and science

question. In the last analysis, it is the olfactory sense which determines whether or not a person who has eaten garlic is guilty of "offensive breath."

In all twelve experiments, the garlic odor unquestionably appeared on the breath. The appearance time varied from twenty to 120 minutes after ingestion of the capsules. The odor increased in intensity for from one to two hours, maintained a plateau of varying duration, and then gradually waned. The longest persistence of odor noted was twenty-six hours. No definite correlation was found between dosage and appearance time, intensity or duration of odor. In five of the experiments on four subjects, the encapsulated garlic was given directly after a large meal, and the results could not be differentiated from those in which the vegetable was taken on an empty stomach. In two instances the garlic odor was detectable in single specimens of urine passed several hours after ingestion of the capsules.

The fact that there was no odor detectable for some time after swallowing the capsules would appear to rule out any contamination of the mouth or throat. Several subjects were asked to belch soon after swallowing the capsules, and at such times a strong garlic odor was momentarily detectable. The transient character of this odor indicates that regurgitation of this sort does not contaminate the mouth. The exhaled air, therefore, would seem to be the source of the garlic odor noted in all these experiments.

2. Another group of experiments leads to the same conclusion. In each of two subjects, 1 Gm. of garlic was thoroughly chewed and then spit out; the breath was immediately and markedly fouled. Vigorous gargling and brushing of the teeth for five minutes with 50 cc. of a 1 per cent solution of freshly prepared chloramine (Chlorazene, Abbott) completely and permanently removed the odor. Three other subjects were now given garlic in capsules in the dose of 1 Gm., and as soon as the garlic odor was detected on their breath the chloramine washing was performed. Although the chloramine odor was sufficiently pronounced to prevent completely the detection of the garlic odor for from twenty to forty-five minutes, the latter was again strongly apparent after the mouth-wash odor faded. The garlic odor is obviously coming from some source not reached by chloramine; i. e., the expired air. It appears that chloramine can remove only that fraction of the garlic odor which is contributed by the mouth contamination by the vegetable and masks but temporarily the part contributed by the volatile oils excreted from the blood through the lungs.

3. Finally, a third group of experiments was performed, suggested by Dr. W. C. Moloney in his communication to *THE JOURNAL* (Sept. 5, 1936, p. 809). We are indebted to Drs. A. H. Morse and Herbert Thoms for the privilege of using the obstetric wards for certain of these tests. In eight women in the first stage of labor, garlic was given orally in capsules in the manner outlined, in doses of from 1 to 1.5 Gm. In each case the breath was previously free of any garlic-like odor. The patients had not ingested solid food for at least four hours. The same results as recorded for the larger group were observed in these cases; the garlic odor was quite evident within twenty to eighty minutes. These eight patients were delivered of living babies from twenty-five minutes to twenty-one hours after ingestion of the capsules. On the breath of six of the eight babies, garlic odor was definitely present. This was verified in each instance by at least four neutral witnesses who had no knowledge of the experiment. Numerous other new-born babies were used as controls, and in no instance was any control baby mistaken for a garlic subject. Anesthesia odors were not involved, as only nitrous oxide-oxygen was used, and then in only four of the cases. The garlic odor persisted on the breath of the infants for from four to twenty hours. In the two negative experiments, one child was delivered twenty-five minutes after the mother took the garlic and at a time when her breath

was as yet but feebly tainted; in the second case the delivery occurred after twenty-one hours, when the mother's breath no longer showed the odor. It must be obvious that the volatile oils in garlic not only accumulate in the mother's blood in sufficient concentration to taint her breath by excretion through the lungs but also to pass the placental barrier and "perfume" the breath of the fetus. The problem of mouth contamination is excluded by these experiments.

From these data, in conjunction with what is already known about the absorption, fate and excretion of the volatile oils of garlic, it is apparent that the garlic breath odor after the oral ingestion of the vegetable is due not only to contamination of the mouth by particles of garlic but also in part to the absorption of these oils from the intestinal tract into the blood, their transportation to the lung capillaries, and consequent excretion into the alveolar air. The latter factor alone, under the conditions of our experiments, can result in fouling of the breath which is not obliterated by specific mouth washes. In the light of this evidence, it appears possible in agreement with Blankenhorn and Richards to answer the postulated question only in the affirmative.

We have discussed at length these results with Drs. Haggard and Greenberg and they agree with us that the problem is largely a quantitative one; that is, that the main and immediate odor after eating garlic is due to mouth contamination and that the odor contributed by the blood depends on numerous factors, all of which determine the final concentration of volatile oil reached in the blood. The most important of these factors, naturally, is the amount of garlic ingested. Again, the expressions "fouling" and "offensive breath" are certainly terms which are open to different interpretations. To have a faint garlic odor on one's breath which can be detected only by intimate contact is obviously quite a different matter than contaminating the air of an entire room.

We have done no experiments with onions, but Drs. Haggard and Greenberg permit us to report their recent finding that 30 Gm. of raw domestic onion can be swallowed in capsules and no odor detected on the breath.

#### SALMONELLA SUIPESTIFER

To the Editor:—The communication from Dr. John R. Mohler in the Nov. 21, 1936, issue of *THE JOURNAL*, the second of two communications on the subject which you have received, referring to an article (*THE JOURNAL*, Aug. 1, 1936) by the undersigned, requires an answer.

The statement at issue in our article is as follows:

Until the World War, the *Salmonella suipestifer* organism was known to be the cause of hog cholera.

We do not feel that any inference can be drawn from this sentence to lead any one to believe that the present-day concept of the etiology of hog cholera is anything else but a filtrable virus.

In our case report we do not raise the issue of filtrable viruses but call attention to the relationship of the organism *Salmonella suipestifer* to human disease.

No statement was made by us as to the transmissibility of hog cholera as such to man but that the secondary invader, so commonly associated with that disease, is of definite pathogenicity for man.

### MEDICOLEGAL ABSTRACTS

**Wills: Dysfunction of Endocrine Glands in Relation to Testamentary Capacity.**—Clara Diesing executed a will bequeathing the major portion of her property to the defendants. She died about a year later and her will was probated. The plaintiffs brought this action to set aside the probate on the ground that the testatrix lacked testamentary capacity. From a judgment in favor of the plaintiffs, the defendants appealed to the Supreme Court of Iowa.

The theory of the case presented by the contestants was that, while the testatrix was not afflicted with any disease of the mind itself, "she was suffering from a congenital faulty development of the body and mind, associated with a perverted activity of the internal glandular system of the body, particularly the pituitary and thyroid glands." To establish their contention, the contestants propounded to expert witnesses hypothetical questions based on the testimony of lay witnesses with respect to the physical and mental characteristics, changes and developments of the testatrix from childhood to shortly before her death. The life history embodied in these questions, said the court, was adequate to form a valid basis for the expression of an opinion by the expert witnesses. Furthermore, the testimony of the expert witnesses, in the opinion of the court, was sufficient to show a permanent progressive impairment of mental as well as physical ability and to indicate that, at the time of the execution of the will, this impairment had proceeded to such an extent that the testatrix was a person of unsound mind and incapable of executing a valid will. The judgment in favor of the contestants was, therefore, affirmed. —*Diesing v. Spencer (Iowa)*, 266 N. W. 567.

**Paternity: Admissibility of Blood Grouping Tests to Determine Paternity.**—The prosecutrix gave birth to an illegitimate baby and the defendant was named as the father. In a prosecution for rape, the defendant asked the trial court to require the prosecutrix and her baby to furnish a few drops of blood for the purpose of having it tested and compared with the blood of the defendant. By this test, the defendant maintained, it might be possible to demonstrate as a scientific fact the impossibility of his paternity. The trial court refused to order the test and the defendant was convicted of second degree rape. On appeal, the Supreme Court of South Dakota upheld the refusal of the trial court to order the test, holding:

"That it does not sufficiently appear from the record in this case that modern medical science is agreed upon the transmissibility of blood characteristics to such an extent that it can be accepted as an unquestioned scientific fact that, if the blood groupings of the parents are known, the blood group of the offspring can be necessarily determined, or that, if the blood groupings of the mother and child are known, it can be accepted as a positively established scientific fact that the blood group of the father could not have been a certain specific characteristic group."—*State v. Damm (S. D.)*, 252 N. W. 7.

A rehearing was granted in the case, limited to the ruling of the trial court with respect to the blood test.

Our former opinion, said the Supreme Court on rehearing, seems to have been widely accepted and understood as a holding that the reliability of the blood test was not as yet generally established or recognized by the consensus of expert opinion in the particular field of science wherein the matter lies. There was no intention in that opinion to express a conviction one way or the other on the abstract question of the reliability of the test as a matter of science. Our former opinion, continued the court, went no further than to hold that the record itself failed to establish the reliability of the blood test. In view of this misunderstanding of the purport of its former decision, the Supreme Court considered it advisable, on rehearing, to state that, in its opinion, the reliability of the blood test is definitely established as a matter of expert scientific opinion entertained by authorities in the field, and that the time has undoubtedly arrived when the results of such tests, made by competent persons and properly offered in evidence, should be deemed admissible in a court of justice whenever paternity is in issue. The foregoing statement was

made because, in the words of the court: "We do not wish any misapprehension as to the views of this court by any possibility to deter other courts from accepting and acting upon a tenet of biological science which we are convinced is now fully ripe for acceptance in medico-legal cases."

All judicial powers, said the court, are vested in the courts, and the judiciary constitutes a separate, distinct and coordinate department of the government of the sovereign state. The primary function of the judiciary is the administration of justice, and justice can never be rightly administered unless truth is first ascertained as nearly as may be. The citizen holds his citizenship subject to the duty to furnish to the courts, from time to time and within reasonable limits, such assistance as the courts may demand of him in their efforts to ascertain truth in controversies before them. This is just as much a part of the citizen's inescapable duty of supporting his government as is military service in time of war, or any other like obligation. The court could perceive no valid reason why courts of record may not require of any person within their jurisdiction the furnishing of a few drops of blood for test purposes when so to do will or may materially assist in administering justice in a pending matter. The order should not issue as a matter of absolute right but in the sound discretion of the court. A trial judge should not be a mere umpire presiding over a game of skill conducted by counsel, and the court could conceive of no valid reason why a trial judge might not of his own motion in a given case, if he thought it likely to be helpful, order the making of a blood test by a competent person and a report thereon under oath subject to cross-examination by both parties. Recapitulating its views, the court said—

We think (1) the reliability of the blood test is universally conceded by competent scientific authorities; (2) a trial court of record in this state has inherent power and authority, in its reviewable discretion, to order the taking of blood for such purposes in cases where paternity is an issue and where, in the opinion of the court, the making and reporting of such test will be, or is likely to be, helpful in ascertaining the truth.

Notwithstanding the foregoing views, the Supreme Court felt impelled to hold that the trial court did not err in refusing to make the order requested. The case, the Supreme Court observed, was tried in October 1931, and the literature on the topic of the scientific reliability of the blood test appeared for the most part subsequent to that date. We are far from willing, the court said, to say that it was error for a trial judge in South Dakota, at the time of the trial of this case, to fail or refuse to take judicial notice of such reliability. If such reliability was not, at the time of the trial of the case, a matter which the trial court was obligated judicially to notice, then it was necessary for the applicant for the order to prove such reliability by proper and satisfactory expert testimony. This he failed to do. Furthermore, there was no adequate showing that if the requested order was granted the defendant could and would have the tests made by a competent, capable and experienced person. The judgment of the trial court was, consequently affirmed.—*State v. Damm (S. D.)*, 266 N. W. 657.

## Society Proceedings

### COMING MEETINGS

- American Academy of Orthopedic Surgeons, Cleveland, Jan. 11-13. Dr. Philip Lewin, 55 East Washington St., Chicago, Secretary.
- American Orthopsychiatric Association, New York, Feb. 18-20. Dr. George S. Stevenson, 50 West 50th St., New York, Secretary.
- Annual Congress on Medical Education, Medical Licensure and Hospitals, Chicago, Feb. 15-16. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.
- Middle Section, American Laryngological, Rhinological and Otolaryngological Society, Chicago, Jan. 11. Dr. Alfred Lewy, 25 East Washington St., Chicago, Chairman.
- Mid-Western Section, American Laryngological, Rhinological and Otolaryngological Society, Chicago, Jan. 11. Dr. Frederick A. Figg, 436 Terry Ave., S.W., Rochester, Minn., Chairman.
- Pacific Coast Surgical Association, Seattle, Wash., and Victoria, B. C., Feb. 24-27. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.
- Southern Section, American Laryngological, Rhinological and Otolaryngological Society, Memphis, Tenn., Jan. 13. Dr. Charles D. Blasingame, Physicians and Surgeons Bldg., Memphis, Tenn., Chairman.
- Western Section, American Laryngological, Rhinological and Otolaryngological Society, San Diego, Calif., Jan. 30-31. Dr. David R. Hight, 324 Fourth Ave., San Diego, Calif., Chairman.

If this patient has not had previous attacks of pneumonia, if he is in good health now, if the physical and x-ray examinations give normal results, it would seem unnecessary to send him away.

If these conditions are not all fulfilled, a change to a more equable climate for one or two winters should be considered.

#### EXTRASYSTOLES

*To the Editor:*—What are present conclusions regarding drug therapy and mode of action in functional cardiac disturbances? An active man of 75 has had noticeable extrasystoles for fifteen years, increasing in frequency and discomfort recently. The blood pressure is 105 systolic, 70 diastolic. The pulse is 70 and very irregular in strength. Quinidine hydrochloride 3 grains (0.2 Gm.) three times a day sometimes relieves and sometimes aggravates symptoms. Does this drug act through the thyroid in such cases? Please omit name.

M.D., California.

**ANSWER.**—To confine the discussion to the specific case described here, it must be pointed out that the extrasystoles may not be on a functional or neurogenic basis.

Extrasystoles may be ascribed to neurogenic and to organic causes. The neurogenic type is common in younger persons, is frequently not associated with other cardiac disturbance and may often be linked up with specific reflex disturbances.

Extrasystoles making their original appearance after fifty years and increasing in severity as time goes on raise a suspicion of organic cardiac disease. Most commonly this consists of ischemic areas of the heart muscle resulting from coronary changes. The case described here would seem to fall into this group.

Quinidine is believed to act on the heart muscle directly and not through the thyroid. It depresses the cardiac irritability and for this reason is the drug of choice in the neurogenic extrasystole. Because it depresses other functions of the heart muscle, it must be used with some care when cardiac disease is present.

The extrasystole that is produced by coronary disease is more likely to yield to the drugs of the theobromine or theophylline group.

Was this arrhythmia confirmed by the electrocardiogram? The question states that the pulse is very irregular in strength. Very frequent extrasystoles are often confused with other arrhythmias, notably auricular fibrillation, and can be differentiated only by the electrocardiogram.

#### THERAPY OF COUGHS

*To the Editor:*—A man, aged 72, has had a chronic cough for more than two years. In the last two months the cough has become much worse. It usually comes on in paroxysms in the evening and the patient expectorates large quantities of greenish mucus of thick consistency. Analysis of the sputum disclosed no acid fast organisms; Micrococcus catarrhalis predominated. Ordinarily cough mixtures and other preparations have no effect. The man has had a mitral insufficiency for several years and bronchitis. I am now considering a bronchiectasis. Any suggestions for diagnosis and treatment, especially to lessen the amount of secretion, will be appreciated.

BENJAMIN GOLDBERG, M.D., Chicago.

**ANSWER.**—The discussion of the "Therapy of Coughs," published in THE JOURNAL, Feb. 1, 1936, might contain a number of useful suggestions for diagnosis and treatment.

#### INABILITY TO EMPTY BLADDER OF ELDERLY PATIENT AFTER PNEUMONIA

*To the Editor:*—A man, aged 85, had a right lobar pneumonia two months ago. Two weeks later he was unable to urinate and was catheterized. For the past six weeks he has needed a retaining catheter. This rubber catheter passes easily; his prostate is apparently normal but still he cannot urinate. Irrigations are clearing up a chronic cystitis; the bladder holds from 6 to 8 ounces and the output is good. He is still in bed, too weak to sit up; his knee jerks are hyperactive and I have diagnosed his case as a cord bladder following pneumonia. Is there any way to overcome this by operation or medication so he can urinate? Please omit name.

M.D., Minnesota.

**ANSWER.**—It is not uncommon for elderly males to develop urinary retention while confined to bed. This should disappear when the patient gets back on his feet. If not, a more thorough urologic examination must be performed, as it is to be remembered that obstruction by the prostate cannot always be determined by rectal examination. Treatment by means of the various drugs used to stimulate neurogenic bladders, such as ergotamine tartrate or mecholyl, should not be tried until the diagnosis of cord bladder is confirmed by cystoscopic or cystometric study. Certainly the treatment of choice in this case is the continuation of drainage by urethral catheter until the patient is out of bed.

#### PERCOL

*To the Editor:*—I have come across a product sold under the trade name of "Percol" which is manufactured by the Ernst Bischoff Company, Inc., 135 Hudson Street, New York City. In looking through the copy of the N. N. R. and its supplement I find no reference either to the product or to the company. According to the pamphlet enclosed with the preparation it is supposedly indicated for "irritating and spasmodic coughs," and its ingredients are listed as:

Piscidia erythrina  
Thymus vulgaris  
Castanea dentata

but the concentrations of each are not given. Piscidia, so far as I can determine, was introduced at one time as a sedative, hypnotic and analgesic, but later it was proved practically useless (Tyrode and Nelson, 1905). The thyme oil, if present in sufficient concentration, is commonly accepted as an irritant. As for the castanea, presumably the fluid-extract, I can find no reference to it in recent pharmacologic textbooks. The product seems to be enjoying quite a popular enthusiasm in this region, both in self medication and in legitimate practice, but I am perplexed as to the rationality of it as a therapeutic agent and wonder whether the foregoing are all of the ingredients. I would appreciate any information that is available relative to the product, as well as references to recent literature, if there are any.

ADAM J. RAPALSKI, Student (Syracuse '38), Nutley, N. J.

**ANSWER.**—Neither the Council on Pharmacy and Chemistry nor the A. M. A. Chemical Laboratory has made an investigation of Percol. The preparation does not stand accepted by the Council for inclusion in New and Nonofficial Remedies nor has the Ernst Bischoff Company requested the Council to consider the product.

Our information regarding the composition of Percol is limited to the inadequate statements appearing in the advertising material issued by the Ernst Bischoff Company. According to this advertising the ingredients of Percol are piscidia erythrina, thymus vulgaris, pinguicula alpina, and castanea dentata. Piscidia erythrina is described in Sollmann's Manual of Pharmacology as "practically useless." Castanea dentata (chestnut leaves), according to the U. S. Dispensatory, "were recommended a half a century ago in the treatment of whooping cough and the superstition still survives to a certain extent. There is, however, no sufficient reason to believe them to possess any therapeutic value except that of a mild astringent which is due to their tannic acid." Thymus vulgaris, of course, supplies the well known oil of thyme. Pinguicula alpina (alpine butterwort) is not described in any of the standard textbooks on pharmacology or therapeutics available to us. From this information it would appear that Percol is an unscientific mixture of obsolescent drugs, the use of which, in the absence of scientific evidence of their value, is not in the interest of rational medicine.

It is interesting to note that the Ernst Bischoff Company for more than twenty years has marketed another treatment for spasmodic coughs. This preparation, known as "Diatussin," is stated to be "an alcoholic extract of the active principles of two recognized medicinal plants indigenous to the Alps"—thymus vulgaris and pinguicula alpina! A note on Diatussin appearing in THE JOURNAL, May 17, 1913 (Propaganda for Reform, Vol. 1, p. 293). More recently, THE JOURNAL published an abstract of a Notice of Judgment (No. 17767) issued by the federal authorities charged with the enforcement of the Food and Drugs Act. This appeared in THE JOURNAL, Jan. 7, 1933, page 58, and called attention to the misbranding of Diatussin and Diatussin Syrup because of false and fraudulent claims. One wonders whether this unfavorable publicity may explain the decision of the Ernst Bischoff Company to add two obsolescent drugs to its Diatussin formula and call the resulting mixture "Percol."

#### FROZEN MILK

*To the Editor:*—My associates and I were much interested in your reply to an inquiry on the use of frozen milk in infant feeding on page 562 of THE JOURNAL for Feb. 15, 1936. In connection with this subject you may be interested in the enclosed reprint, "The Food Value of Frozen Evaporated Milk," by Louder and Smith, from the Journal of Dairy Science, March 1932. You will note that the Louder and Smith study is not in absolute agreement with the statement in THE JOURNAL. Would you favor us with the reference in the literature on which the statement in THE JOURNAL is based?

CHARLES DILLON, Evaporated Milk Association, Chicago.

**ANSWER.**—The references in the literature on which the statement in THE JOURNAL is based are found in "Milk," by Paul G. Heineman (Philadelphia, W. B. Saunders Company, 1919) and "Principles and Practice of Infant Feeding," by Julius H. Hess (Philadelphia, F. A. Davis Company, 1922).

On page 87 of the latter, in the paragraph on frozen milk, it is stated that "vomiting and not infrequently diarrhea follow the feeding of milk that has been frozen. So far as possible,

matory processes and infection that accompany the malignant condition. Treatment with divided doses of radium affords a good opportunity to forestall or control these complications. The treatments are given gradually during three weeks and the dosage is attuned to the radiosensitivity of the lesion and to the strength of the individual to tolerate the procedure. At the first intimation of danger, the treatment should be discontinued and the proper steps should be taken to overcome the impending complication.

**Radiation Sickness.**—In their search for an extraneous factor other than ozone or other gases as the cause of radiation sickness, Friedman and Drinker determined the ion concentration of their treatment rooms and the quantity and quality of the gases present. These experiments showed a high concentration of ions with the positive ions predominating and traces of ozone and nitrous gases; the probability of any one or all of them being a cause of radiation sickness could be determined easily. Through a number of experiments it was found that by wearing a simple type of mask, one that was known to absorb ozone and other gases, several patients who were subject to radiation sickness were relieved. A commercial make of chemical cartridge respirator with a charcoal cartridge was furnished to one patient and gave her immediate relief. The cartridge containing charcoal was replaced by wire cloth of a very fine mesh, which was inserted at the entrance to the mask and grounded. This device was found to be just as satisfactory as the mask with charcoal. The experiments tend to show that of the air factors only ions enter into the production of radiation sickness. These in high concentration in addition to roentgen irradiation to the body are necessary for the production of true radiation sickness. The factor of gases has been eliminated. A mask with a rubber face piece and wire cloth is the simplest and cheapest. The face piece can be wiped off with alcohol or washed and reused immediately. It is advisable to use a face piece with both inhalation and exhalation valves, as then there is no rebreathing.

- Tuberculous Tracheobronchitis: Role of Bronchoscopy. P. S. Samson, Ann Arbor, Mich.—p. 671.
- Anthracoilicosis and Tuberculosis. M. J. Sokoloff, Philadelphia.—p. 700.

**Influence of Artificial Pneumothorax on Bacillary Count in Pulmonary Tuberculosis.**—Bunta discusses the influence of artificial pneumothorax, in relation to time, on the bacillary count preceding conversion in positive sputum cases of pulmonary tuberculosis, particularly those showing unilateral cavitated lesions with and without complicating pleural adhesions on the collapsed side, and those showing bilateral pulmonary cavitation. The material for study included 13,839 sputum reports on 506 pneumothorax-treated open cases of pulmonary tuberculosis, and 4,993 sputum reports on 642 officially registered open pulmonary cases in which no form of collapse therapy was given. A decrease in the bacillary count with increments of time was observed in both pneumothorax-treated and nonpulmonary collapse or control patients. Pneumothorax-treated patients in general showed a more direct and sustained decrease in the number of tubercle bacilli and advancement toward the conversion level with elapsing time, as compared to the control group. All treated cases, except the group with bilateral pulmonary cavitation, showed a more direct reduction in bacillary numbers from the seventh to the ninth month than in the succeeding months of treatment. From the standpoint of time, the most direct decrease in the bacillary

count and earliest approximation to the conversion level was evidenced in nonpleural adhesion cases with cavities limited to the treated lung, and the least diminished count or approach to the conversion level in the pneumothorax cases with bilateral pulmonary cavitation. Pleural adhesions, on the other hand, exercised an inhibiting influence on bacillary reduction, though relatively less so than the cases with bilateral cavitation.

**Punch Biopsy in Diagnosis of Tuberculosis of Knee.**—Burman and his associates obtained six biopsy specimens positive for tuberculosis in eight cases of tuberculosis of the knee joint, through the same puncture wound used for arthroscopy. In a woman of 35, who had been treated for villous synovitis for two years, a frozen section of the biopsy specimen revealed the presence of tuberculosis and an immediate fusion was accordingly done. No guinea-pig inoculation or tuberculin test had been done previously in her case. The biopsy specimen is a tolerably accurate measure of the specificity or non-specificity of the disease process within the joint. It is sometimes quite difficult to prove the tuberculous nature of the disease process in the knee joint. Any method that offers a fair chance of success, both negatively and positively, should be used. Guinea-pig inoculation and the demonstration of the tubercle bacillus are the only other positive methods, besides the histopathologic picture of tuberculosis. The authors procure material from a joint suspected of being tuberculous for culture and guinea-pig inoculation by using the saline washings of the joint, after the fluid has been instilled into the joint for some minutes. In a child in whom the removal of a biopsy specimen was objected to, the saline washings injected into a guinea-pig confirmed a suspected diagnosis of tuberculosis. They can offer no exact figures of failure or success; but, if it succeeds once, it can succeed again, especially in joints without fluid. The trauma of examination by arthroscopy followed by the removal of biopsy specimens is not damaging to the knee. In two acutely inflamed joints, these procedures were done without perceptible alteration in the state of the joint or alteration of the temperature curve for the worse.

CONNECTICUT: *Basic Science*, New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical (Homeopathic)*, Derby, Feb. 13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven. *Medical (Regular)*, Hartford, March 9-10. *Endorsement*, Hartford, March 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.  
DISTRICT OF COLUMBIA: Washington, Jan. 11-12. Sec., Commission on Licensure, Dr. George C. Rulland, 203 District Bldg., Washington.  
IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. Emmitt Pfost, 205 State House, Boise.  
ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.  
INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.  
IOWA: *Basic Science*, Des Moines, Jan. 12. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames.  
MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.  
MINNESOTA: Minneapolis, Jan. 19-21. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.  
MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.  
NEBRASKA: *Basic Science*, Omaha, Jan. 12-13. Director, Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.  
NEVADA: *Reciprocity*, Carson City, Feb. 1. Sec., Dr. John E. Worden, Carson City.  
NEW HAMPSHIRE: Concord, March 11-12. Address Board of Registration in Medicine, State House, Concord.  
NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward Box 693, Santa Fe.  
NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.  
PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.  
SOUTH DAKOTA: Pierre, Jan. 19-20. Dir., Division of Medical Licensure, Dr. B. A. Dyar, Pierre.  
VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.  
WASHINGTON: *Medical*, Seattle, Jan. 11-13. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.  
WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.  
WISCONSIN: Madison, Jan. 12-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.  
WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*, Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. *Part III*, New York, Jan. 11-13 and Chicago, Jan. 19-21. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

#### SPECIAL BOARDS

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held simultaneously in different centers of the United States and Canada in March. *Practical examination* will be given in St. Louis in April and at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210 Des Moines.  
AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the United States and Canada, March 6. *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. *Applications must be received at least sixty days prior to the examination dates*. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).  
AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.  
AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.  
AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.  
AMERICAN BOARD OF PEDIATRICS: New York, Jan. 23. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

### Michigan June Examination at Ann Arbor

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports the written examination held at Ann Arbor, June 11-12, 1936. The examination covered 14 subjects and included 1,000 questions. An average of 75 per cent was required to pass. One hundred and twenty-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent.
College of Medical Evangelists.....	(1936)	82	85
Stanford University School of Medicine.....	(1935)	83.5*	(1936) 84.8

### Michigan June Examination at Detroit

Dr. J. Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports the written examination held at Detroit, June 9-10, 1936. The examination covered 14 subjects and included 1,000 questions. An average of 75 per cent was required to pass. Ninety-seven candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent.
College of Medical Evangelists.....	(1936)		84.9
Loyola University School of Medicine.....	(1936)		83.1

### Tennessee September Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Memphis, Sept. 29-30, 1936. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Twenty-eight candidates were examined, 27 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent.
Loyola University School of Medicine.....	(1935)		83.4
Tulane University of Louisiana School of Medicine.....	(1936)	85.3,	85.9
University of Tennessee College of Medicine.....	(1936)		80.9,
82.5, 82.6, 82.8, 83.3, 83.9, 84.1, 84.5, 84.6, 84.8,			
84.9, 85.1, 85.3, 85.3, 85.3, 85.4, 85.4, 85.8, 86.8,			
87.8, 88.3, 88.4, 90.9			
Vanderbilt University School of Medicine.....	(1935)		88
School	FAILED	Year Grad.	Number Failed
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin.....	(1910)*		1

Twelve physicians were licensed by endorsement from September 1 through October 31. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1935), (1936), 2) N. B. M. Ex.		
Rush Medical College.....	(1931)		Illinois
Tulane University of Louisiana School of Medicine.....	(1933)		Louisiana

be hemoglobin or its derivatives. The blood pressure was not elevated, and generalized edema appeared in two patients, but only after infusion of large amounts of saline and dextrose solutions. While the ultimate cause of some of the manifestations must be considered as still unexplained, there can be little doubt that the syndrome is initiated by hemolysis of the donor's red blood cells. There is a striking similarity to the suppression of urine and uremia seen in cases of severe black-water fever, even with regard to the histopathologic changes in the kidneys. The essential lesions consist of tubular dilatation and some degeneration (particularly affecting the epithelium of Henle's loop and the distal convoluted tubule) with interstitial edema, a picture suggestive of mercurial nephrosis. The degree of tubular damage observed varies with the time of death. The distinctive feature is the formation of peculiar obstructing pigment casts in the distal tubular segments. The changes observed in the tubules in the fatal cases apparently represented late stages in the events following a hemolytic reaction. The peculiar eosinophilic casts present in the convoluted tubules and in the Henle loops must contain hemoglobin or one of its degradation products, because of the color of these casts in unstained sections and their positive reaction with benzidine by Lepelne's method for staining hemoglobin in histologic preparations.

**Tuberculosis of Breast.**—Hall cites three cases of tuberculosis of the breast that demonstrate the pathologic mode of invasion and infection. To date there has been no report of a necropsy in which tuberculosis has been confined to the breast with no evidence of infection elsewhere. The disease appears most frequently between the ages of 20 and 50. There is little difference with regard to the breast involved. Child bearing does not appear to be a gross factor, since 201 of 545 were nulliparous patients. It has been the belief of many that this type of infection is due to the bovine type of tubercle bacillus. The infection is transmitted to the breast tissue by various channels: contiguity, surface contact, ductal, blood borne and lymphatic. Tuberculosis of the breast is similar to the infection elsewhere in the body, as acute milary mastitis, nodular tuberculous mastitis, sclerosing tuberculous of the breast and chronic obliterative tuberculous mastitis occur. Excluding those patients who are evident victims of a generalized infection, tuberculosis of the breast may be subdivided according to the rate of involvement and to the fibrous tissue

response. The signs and symptoms vary widely, but the first and most important is a lump in the breast. Pain usually appears very late in the disease and was reported in only 6 per cent of the early cases. An occasional early complaint is that of tender nipple. The lump usually develops steadily, sometimes rapidly, and in no case has spontaneous regression been known. The disseminated nodular type grows very slowly and is painless. The sclerosing type exhibits a distorted breast with retracted nipple. Definite diagnosis is difficult at all times and must be differentiated from galactocoele, chronic mastitis, and benign and malignant breast tumors. The prognosis is hopeless if untreated, usually following a rapid and fatal course, but if the lesion or lesions are excised totally it may be excellent. Treatment is always surgical, with immediate frozen section to establish the diagnosis and remove the patient's fear of cancer; also removal is essential, as the disease, once started, never regresses, whether it is left alone or treated by any of a number of means. Excision of the tumor, dissection of axillary glands and partial mastectomy may be satisfactory if the lesion is benign or if the diagnosis of tuberculous of the breast is reasonably certain as determined by biopsy or culture of the pus from a sinus, or if the operation is supplemented by frozen section. Summarized, excision of tuberculous breast lesions together with whatever obvious lymphatic extensions are present will be quite satisfactory. If a considerable part of the breast is involved, mastectomy is advised. If there is any suggestion of axillary involvement, these glands should be removed. Only healthy tissue should be left, careful hemostasis effected and well nourished tissue brought in contact with well nourished tissue, obliterating all dead space. Drains, if used, are removed the first day after operation. An immobilizing bandage, affording light pressure, is applied, and, when possible, the wound is left alone for from twelve to fourteen days.

**Old and New Insulin in Treatment of Diabetes.**—Joslin has computed the expectation of life of his diabetic patients at 10, 30 and 50 years of age for two periods, 1897-1914 and 1926-1929. For children at 10 years in the earlier period the average expectancy was 1.5 years, but now it is 31.7 years. The expectancies for the two similar periods at 30 years of age are 4.2 and 22.7 years, and for the age of 50 years 8.1 and 13.2 years, respectively. A study of the records of diabetic physicians shows that it is worth while to teach a diabetic patient a good deal about his ailment. Since the introduction of insulin, diabetic coma has practically disappeared as a cause of death among physicians. It has amounted to but 3 per cent. This is all the more notable because diabetic coma when it develops in adult life is a serious complication, and recoveries are far less frequent than in childhood. The education of diabetic patients can be accomplished by books, moving pictures, class teaching and individual instruction, but perhaps most of all they can profit from contact with other patients. The personal element and the spoken word are the most important, because what one type of diabetic subject needs would be superfluous for another. Of more than 100 patients receiving protamine insulin not one has developed coma, acidosis or any complication common to the diabetic, such as lesions of the feet or skin. The number of doses has been reduced from six to one or two daily. The author considers protamine insulin a real advance in the treatment of diabetes, but he does not believe that the best methods of employing it are known, nor does he think that it should be distributed yet for general use. The old insulin is understood and it is known that it always works. Confidence in insulin must not be undermined by giving to practitioners a preparation the action of which is not thoroughly understood, though it may be better in some respects. The technic of manufacture of protamine insulin is improving and the results with the newer preparations are becoming more uniform. Administration of protamine insulin can be improved. It is not a matter of indifference to inject 20 units of old insulin twice a day and then change over to the injection of 40 or 50 units of protamine insulin in a single dose. More pains must be taken with the actual technic of injection, and the sites for the injection must also be selected more carefully. The strength of the preparation may be important. The single doses of protamine insulin are larger and therefore U-40 insulin is too bulky, but just how U-80 protamine insulin will act the author does not know. Perhaps one should never inject more

of obstetrics as it is regarded at this time. He mentions only to condemn the time honored custom of massaging the uterus after delivery, as well as the less harmful custom of holding the fundus. Nothing is gained, he says, by either practice and much harm from unnecessary traumatism may result. We are told that episiotomy was proposed by Ould as early as 1742 and has been followed "more or less" ever since. The author considers episiotomy valuable but by no means necessary in all patients. It is said that multiple births must be regarded as a reversion to lower mammalian forms and therefore in a measure pathologic. Since the Dionne quintuplets were born, there has come to light, it appears, the birth certificate of a family of sextuplets named Bushnell, who were born in Chicago, Sept. 15, 1866, which birth certificate, "if genuine," states that three boys and three girls were born. Of the six, three were living in January 1935, a fourth died a few years ago, and the two others considerably before, but all lived beyond infancy. Statistics are said to show that 3 per cent of cesarean scars rupture in succeeding labors, but these figures are subject to much correction. While the average gross maternal mortality following cesarean section, the author says, is somewhere near 10 per cent in the United States, the mortality in the great clinics of the country will range between 2 and 4 per cent. The elective cesarean section, if done before the onset of labor or immediately after labor in a well organized hospital, will carry a mortality of considerably under 1 per cent, but in the section of necessity, in neglected cases, this figure will rise to 6 or 7 per cent.

The author endeavors to avoid the use of proper names throughout the book but has appended a bibliography and index in the back. This book can be recommended for students and practitioners of medicine.

**Chemie und Technik der Gegenwart.** Herausgegeben von Dr. H. Carlsohn, Dozent an der Universität Leipzig. Band XV: Vitamine und Hormone und ihre technische Darstellung. Teil 1: Ergebnisse der Vitamin- und Hormonforschung. Von Dr. Hellmut Bredereck, Dozent an der Universität Leipzig. Paper. Price, 6 marks. Pp. 101. Leipzig: S. Hirzel, 1936.

The author of this treatise has attempted to cover the extremely difficult subjects of the chemistry of vitamins and hormones in the brief compass of a hundred page book. Considering the limitations of space and the voluminous literature on the subject, he has managed to include a surprising amount of valuable information; those desiring such a brief summary will find this book useful. Certain phases of the material considered here are more adequately presented elsewhere, in particular that relating to the sterols (vitamin D, estrogens, androgens, progesterone and the like); the recently published American monograph on the latter subject by Fieser (*Chemistry of Natural Products Related to Phenanthrene*, reviewed in *THE JOURNAL*, Aug. 29, 1936) is unsurpassed in any language. However, for a brief and graphic presentation of the broad fields of vitamins and hormones Bredereck's condensation may be recommended, provided the limitations of brevity are kept in mind.

**The Fortieth Report on Food Products and the Twenty-Eighth Report on Drug Products, 1935.** Connecticut Agricultural Experiment Station, Bulletin 388. Paper. Pp. 653-695. New Haven, 1936.

This is a brief summary of the control work and investigation during 1935 of the Department of Analytical Chemistry at the first experiment station to be founded in the United States. As usual, the bulletin of the Connecticut station contains information of interest to all health officials and to physicians and others interested in nutrition. There are tables showing the vitamin C content of orange juice and other orange products as determined by chemical titration, investigations on olive oil, spray residue on apples, an interesting statement on oranges bearing the stamped mark "color added" and numerous other items of interest. A number of drugs were tested to ascertain whether they came up to standard; it is encouraging to note the large number of products examined which were found satisfactory. There are brief summaries of the analyses of a number of "patent medicines" and cosmetics that were examined. The range of subjects covered is wide. The composition of a number of fruits of wild plants on which birds and other animals feed was determined in collaboration with the Bureau of Biological Survey. The report closes with a

splendid description of the work of the Committee on Foods, now called the Council on Foods, of the American Medical Association.

**On the Classification of *Vibrio Cholerae* and the Cholera-Like Vibrios.** By Børge Helberg. Translated from Danish by Dr. Gerda Seldelin Schnohr, with the assistance of Dr. G. Gregory Kayne. Paper. Pp. 181. Copenhagen: NYT Nordisk Forlag: Arnold Busck, 1935.

This study was conducted on the suggestion of Dr. Thorvald Madsen following a meeting in 1932 of the cholera committee appointed by the Office international d'hygiène publique, at which was discussed the problem of producing a standard cholera agglutinating serum for diagnostic purposes. A study was made of 384 strains collected from districts where cholera and cholera-like diseases are epidemic. Biochemical as well as agglutination tests have been made with these strains. The author concludes that at the present time it does not seem possible to produce a standard agglutinating serum, since many vibrios termed cholera-like have not been demonstrated to be pathogenic or to produce the clinical picture called Asiatic cholera. This work contains forty-three tables and a good bibliography.

**Brain Reflexes and Laws of Existence.** By William D. Hoffman. Cloth. Price, \$10. Pp. 308. Los Angeles: Parkman Press, 1936.

This volume "endeavors to make clear all the branches of human actions and reactions, not only as applying to therapeutic principles, but to glimpse the principles that operate the universe" (p. 7). An ambitious aim, surely. But the informed reader closes the book with the conviction that the author has not been equal to either task. The central theme of the book is the well known fact that a happy and hopeful state of mind is favorable in the recovery from disease. But this well known principle, whatever the physiologic mechanisms may be, is so exaggerated by the author as to make fear a cause of cancer and relief from fear a cure of cancer. The author's mastery of neurology, physiology, physics and chemistry is not striking. His explanations of man's behavior in health and in disease are mainly verbalism. That a doctor's "personality" is a factor in inducing confidence and hope in his patients and that the latter are favorable to recovery is true, but why run this truth into the ground by making it a panacea? We do not serve science or society nor do we discourage quacks by going the latter 50-50 in unproved claims.

**Aktive Entspannungsbehandlung: Ein neues therapeutisches Prinzip mit Berücksichtigung der Sprache und Atmung.** Von Dr. med. Joh. Faust. Boards. Price, 5 marks. Pp. 112, with 20 illustrations. Stuttgart & Leipzig: Hippokrates-Verlag G. M. B. H., 1936.

This brochure deals with so-called active relaxation. Voluntary muscular relaxation is now well founded by physiologic experimentation and it seems to be of some therapeutic significance. The author attempts to show that the training of relaxation is in no way related to the methods of suggestion or hypnosis. He prescribes relaxation for various neuroses, especially those involving the breathing apparatus.

**Urology in Women: A Handbook of Urinary Diseases in the Female Sex.** By E. Catherine Lewis, M.S., F.R.C.S., Surgeon to the Royal Free Hospital, London. Second edition. Cloth. Price, \$2.25. Pp. 100, with 31 illustrations. Baltimore: William Wood & Company, 1936.

This small monograph discusses in an excellent manner those urologic lesions which in a particular manner affect women. In this edition, sections are devoted to vesical neck obstructions and to endometriosis. Treatment has been accorded greater space and amplified discussion of the ureteral changes in pregnancy, and of prolapse and dilatation of the ureters, is acceptable. The illustrations are excellent and the arrangement and physical aspect of the book all that could be hoped for. The book will prove of value as a work of reference and will be especially appreciated by the experienced urologist and gynecologist.

**Tonzilyarni zakhvoryuvannya: Khronichnyi tonzillit, khroniosepsis, sepsis pilsya angini.** [By] A. I. Geshelin. [Tonsillar Infection: Chronic Tonsillitis, Chroniosepsis and Postanginal Sepsis.] Paper. Price, 1 ruble, 20 kopecks. Pp. 95. Kiev: Derzhavne medichne vidavnistvo, 1936.

This is a monograph written in the Ukrainian language. It contains chapters on the anatomy, pathology, bacteriology and treatment of tonsillar infections. The author discusses sepsis of tonsillar origin and reviews the various concepts. The subject matter is well presented and the field is adequately reviewed.

are not increased in infectious mononucleosis; namely, rabbit, pig, dog and guinea-pig. The most reliable method besides the absorption of sheep agglutinins by rabbit blood corpuscles (Stuart) is the absorption of horse agglutinins by beef blood corpuscles. By the first method, almost no absorption of the agglutinins is obtained in infectious mononucleosis; by the second, almost complete absorption. In normal serums and in serums after the injection of serum the reverse is true. The differential diagnosis of infectious mononucleosis cannot always be made serologically after the injection of serum.

**Peripheral Blood Flow in Surgical Shock.**—Freeman and his co-workers stabilized the metabolic demands of the tissues of the hand by maintaining it at a constant temperature. Traumatic stimuli such as cold, pain and fear produced a decrease in the volume flow of blood. With asphyxia, a variable effect was observed. In the hand with vasomotor control intact a decrease in blood flow was observed in six cases, while an increase in circulation was found in eleven cases. The blood flow decreased in regions subject to vasomotor control. It was simultaneously increased in the sympathectomized hand. The systolic blood pressure was raised but slightly, while the diastolic blood pressure more frequently was lowered during the period of asphyxia. In the twelve experiments in which the blood pressure was determined, the maximal rise in systolic pressure was only 10 mm. of mercury. The flow of blood is modified by the metabolic demand of the tissues. Two forces are therefore simultaneously called into play—reflex vasoconstriction and local vasodilatation. The final result depends on which of the two forces is dominant. When the subject was apprehensive, a decreased blood flow was generally observed. In asphyxia not only does the reduced oxygen saturation of the arterial blood necessitate a more rapid circulation but through reflex vasoconstriction the supply of blood at the same time may even be reduced. In the more severe cases of shock the oxygen saturation of the venous blood was below 50 per cent. The inability of the tissues to obtain an adequate supply of blood was indicated by the observations on reactive hyperemia. In the normal subject the circulation increased rapidly after release of the tourniquet. In patients who were in shock a comparable increase was not observed. If the blood volume is reduced, the blood pressure may still be sustained by increasing the peripheral resistance through vasoconstriction. With vasoconstriction, however, the nutrient flow to the tissues becomes reduced. The use of epinephrine or ephedrine in the treatment of surgical shock furnishes an example of this fact. The blood pressure may be increased, but only at the expense of the blood flow. When the lowered blood pressure is the result of a reduced volume of blood in the vascular bed, physiologic treatment necessitates the administration of blood or some blood substitute. The reduced blood flow in the hand, observed in clinical cases of surgical shock, represents a deficiency of circulation that is probably general throughout the body. If the reactions to a crisis are too severe and protracted, vasoconstriction, the very mechanism by which the organism strives to survive, may lead to its destruction.

**Glycemic Response to Protein and Carbohydrate.**—Conn and Newburgh show that ingested protein causes a very much smaller increase in the blood sugar than results from an equivalent amount of dextrose or carbohydrate food. They believe that the explanation involves a principle that has received but little attention. One is accustomed to measure the capacity of a diabetic patient to dispose of dextrose in terms of the total number of grams of dextrose released from his diet in twenty-four hours. The number of grams of dextrose that just fails to produce glycosuria is taken to be a measure of the largest amount of dextrose that the patient can utilize in a period of twenty-four hours. Since maximal tolerance without glycosuria depends on the rate at which the body is able to remove dextrose from the blood stream by oxidation, deposition as glycogen and transformation to fat, the time element assumes an importance at least equal to that of total yield of dextrose in grams. During the metabolism of protein there occurs a slow yield of dextrose, which approximates 50 per cent of the weight of the ingested protein. Since protein in the diet represents a large source of dextrose, a comparison was made between the blood sugar levels and glycosuria produced by ingestion of equivalent amounts of dextrose derived from

protein and from dextrose and carbohydrate foods. The studies were made on fifteen diabetic patients and three normal fourth year medical students. Each subject was maintained aglycosuric for at least two weeks before the study was begun. In the process of protein metabolism, the complex protein molecule is split in the intestinal tract to amino acids. These are absorbed into the blood stream and transported to the liver, where oxidative deamination occurs. Here the glycogenic amino acids are split to form urea and dextrose. That this process is a slow one is shown by the slowly rising blood urea nitrogen. Dextrose is therefore liberated into the blood stream in this process at a slow and even rate over a prolonged period. Under these conditions the diabetic patient is able to utilize a greater total amount of dextrose without glycosuria in a period of eight hours. Therefore the inability of a diabetic subject to dispose of large quantities of dextrose is partially compensated if the dextrose is presented for utilization slowly and evenly. There appears, then, to be some advantage to the patient in this slow liberation of dextrose from protein foods.

**Blood Grouping in Forensic Medicine.**—Gettler and Kramer admonish against the use of blood grouping of partially decomposed (and contaminated) blood stains, since their experiments showed discrepancies. Fresh blood samples of known groups were smeared on cloth, paper and metal implements and allowed to stand for various intervals. The dried blood stains were then again tested. When putrefaction of the blood samples set in before they dried, as many as fourteen out of eighteen wrong groups were obtained. Not only were agglutinin or agglutinin destroyed during the drying or aging of the blood stains, but in some instances changes occurred which yielded reactions simulating those of some particular agglutinin.

### AMERICAN

The Association Library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (\*) are abstracted below.

**Iliac Lymphadenectomy and Irradiation in Cancer of Cervix.**—Taussig has combined irradiation of the primary lesion with surgical removal of a large portion of the tributary lymph glands in forty-six cases of borderline cancer of the cervix. The first case, done in October 1930, with cancer metastasis in the hypogastric lymph glands, is still free of recurrence. Careful selection of cases is a prime requisite to success. The patient must be a good operative risk. Disease of the heart or kidneys, obesity, debility and extreme age are contraindications. There have been two deaths among the forty-six patients operated on. Recently when heavy irradiation preceded the operation the author found that the lymph glands were more likely to be adherent and difficult to remove. Hence he advises from 1,000 to 1,500 roentgens of high voltage therapy spread over two weeks. Two weeks after this series is concluded, iliac lymphadenectomy is done. Two weeks after operation an intra-uterine application of 150 mg. of radium in gold capsules totaling from about 4,000 to 5,000 mg. hours is made. An additional 2,000 to 2,500 roentgens of high voltage therapy should follow the radium treatment. Glandular metastasis was found fifteen times in the forty-six cases. In these cases 194 glands were removed and subjected to careful microscopic study. Of the nineteen patients operated on two or more years ago, compared with seventy-six patients treated with a similar dose of radiation but without lymph gland removal, the survival curve remains definitely higher in the group of lymphadenectomies. Of ten patients treated more than four years ago compared with thirty-five patients whose cancer showed the same stage of involvement not operated on but irradiated by the same method during the same period, the percentage of survival was found to be approximately twice as great in the operative cases as in those in which irradiation alone was given. His experience of the last five years has convinced the author that iliac lymphadenectomy in the hands

of a competent surgeon, done on patients that are good operative risks with only partial cancerous involvement of the broad ligaments, is a relatively simple and harmless procedure and gives an increased chance of survival and cure that definitely justified the surgical intervention.

**New Arsenical in Treatment of Trichomonas Vaginitis.**—Bland and Rakoff used sodium methylenesulfonaminohydroxyphenylarsonate in the treatment of 100 cases of Trichomonas vaginitis. Studies in vitro indicated that the compound has a definite trichomonadocidal power, which is many times that of acetasone and is not inhibited by human blood serum. Treatment consisted of the insufflation of 0.5 Gm. of the drug, diluted with kaolin, following preliminary cleansing of the vagina and vulva with a diluted tincture of green soap and water, and instillation of tincture of metaphen into the cervix and of aqueous solution of metaphen, 1:500, into the urethra. Ninety-one women remained free from Trichomonas vaginitis during a period of from three to nine months following treatment. Of the eighty-four women who remained negative after a series of six treatments, five required an additional series of six treatments and two were cured after two additional series of treatments. Of twenty-five women treated by a similar technic with acetasone, only twelve remained free from Trichomonas vaginitis while thirteen had repeated recurrences. Clinical experience and laboratory studies indicate that the new drug is superior to acetasone in the treatment of Trichomonas vaginitis.

**Complications of Carcinoma of Cervix.**—Bowing and Fricke planned radium treatment for 495 patients who had carcinoma of the cervix. In about 90 per cent of these cases the lesions were inoperable. In spite of careful studies of each patient and the planning of treatment that would not unduly tax the patient's reserve, major complications occurred in 5.6 per cent of these cases, and death occurred in six cases. Much in the way of prevention of serious pelvic cellulitis and peritonitis can be accomplished by daily cleansing of the cervical lesion if considerable infection is evident. Hemorrhage requires more vigorous management. Rectovaginal or vesicovaginal fistulas are rarely seen except as a late result of the malignant process. Proctitis is another serious complication which often is attributable to irradiation, although it may result from perirectal extension of the growth. Lymph stasis with edema of one or both legs is occasionally encountered in late stages of the disease, in cases in which massive infiltration and a "frozen pelvis" are present. Rest and elevation of the part, and the administration of sedatives offer some alleviation. Elevation of temperature, which frequently is seen in the course of treatment, in most cases is the result of the infected cervical lesions. Major complications usually are the result of acute inflam-

**Treatment of Chorea with Vaccine.**—Weisman and Leslie treated fifty children who had moderately severe to violent chorea with New York City typhoid paratyphoid vaccine or its equivalent. The initial dose is always 0.05 cc. of undiluted vaccine, intravenously. Tolerance to the vaccine increases with each day's treatment in the large majority of cases. A dose that produces the first day the satisfactory temperature of 105 F. will in all probability produce only the unsatisfactory temperature of 103 F. the next day. Therefore the dosage must be constantly increased in accordance with the patient's previous reactions. The treatment should be given daily and stopped only when all the signs of chorea have disappeared except for the commonly found residual hypotonia. If seven or eight consecutive treatments do not effect a cure, the child should be given a rest for from two to four days before resuming treatment. On the first day of the second series of treatments the same dose should be used as that of the last day of the first series. The child generally loses from 1 to 4 pounds (0.4 to 1.6 Kg.) during the period of treatment. Patients are given a nourishing high caloric and high vitamin diet, and occupational therapy. The treatment should not be undertaken unless it is possible for all the nursing orders to be carried out in a meticulous fashion. The average duration of symptoms from the inception of treatment was 12.2 days for the moderate group, 13.8 days for the severe group and 22.5 days for the violent group. The average length of hospitalization was twenty-six days for the moderate group, 28.4 days for the severe group and forty-two days for the violent group. Children who had an elevated sedimentation rate after their course of treatment were kept in bed until the rate became approximately normal. In the twenty-two cases of clinical rheumatism, the average duration of chorea was 11.7 days, the hospitalization period twenty-six days and the number of treatments eight. On discharge, forty-six of the patients, or 92 per cent, were completely symptom free. Five of the patients have had a total of six recurrences in the follow-up period of from one to three years.

**Postoperative Derangements of the Gastro-Intestinal Tract.**—Sar-Louis suggests that the mild form of postoperative gastro-intestinal motor disturbance, "gas pains," is caused by the excessive stimulation of the splanchnic nerve, whereas the

severe manifestation, paralytic ileus, represents an advanced stage of the same disturbance which has resulted in a paralytic reaction to excessive stimulation. If gas pains are the result of increased peristalsis from vagus stimulation, drugs that augment intestinal movements are contraindicated. They are of value, however, in the severe forms of motor disturbances due to vagus paralysis. Prophylactic treatment consists of avoiding preoperative purges, careful operative technic and the postoperative avoidance of liquids by mouth. Prevention of dehydration and loss of inorganic salts, as well as restoration of the acid-alkali balance, are accomplished by suitable solutions administered subcutaneously and intravenously. Drugs that have been shown to stimulate the small intestine include hypertonic saline solution administered intravenously, dimethyl carbamic ester of hydroxy phenyl-trimethyl ammonium methyl sulfite, the physostigmine derivative, oil of tansy, acetylcholine and morphine.

**Roentgen Consideration of Gliomas.**—Schwartz analyzes the operatively proved gliomas that had preoperative roentgen examinations at the Neurological Institute during the last ten years. The recognition of a glioblastoma multiforme depends on a short malignant history and evidences of intracranial disease. Untreated these tumors result fatally within about a year, but with the application of from 2,500 to 4,000 roentgens in divided doses the survival time may be doubled, with an occasional remission of symptoms. The astrocytoma constitutes about 30 per cent of the glioma group. Its location can be estimated closely from the study of stereoscopic films. The roentgen diagnosis of an astrocytoma in a child depends on a history of a few months of gradually progressive symptoms, signs of increased intracranial pressure, and little or no atrophy of the sella turcica. In the adult there is a history of many months, even years, of gradually progressing symptoms with perhaps remissions, signs of increased intracranial pressure, a shift of the pineal body, atrophy of the sella turcica, and stricture or punctate deposits of calcium usually situated in the like or punctate deposits of calcium usually situated in the temporal lobe or in the temporo-frontoparietal region. Postoperative empirical irradiation is to be advised. Medulloblastoma is of rapid growth and has the tendency to spread widely through the leptomeninges. The only roentgen evidence of its presence is usually increased intracranial pressure. The medulloblastoma will have a short malignant history and is sensitive to x-rays. The astroblastoma is found almost without exception in the cerebrum of adults and grows rapidly. Cystic degeneration is common and it calcifies frequently. X-rays are of about the same efficiency as in the treatment of a glioblastoma multiforme. The oligodendroglioma is found with but few exceptions in the cerebral hemispheres of adults of from 40 to 50 years of age. The tumors are solid, not apt to become cystic or degenerate, and fairly well demarcated from the surrounding brain tissue. Calcification is usually found to be perivascular, streaky or somewhat flocculent. Roentgen therapy

and basal ganglions following the use of nitrous oxide-oxygen anesthesia. Death during nitrous oxide-oxygen anesthesia has occurred following narcotics of varying duration. In some instances the duration of the narcosis is not given, but it can be assumed that it was not long, since the anesthetic was used for minor operations; for example, extraction of teeth. In fatal cases the respiration ceases suddenly and without warning. The relation of the failure of circulation to that of respiration varies. Three of the authors' cases belong to the group with a fatal outcome after hours, days or weeks. The respiration ceased suddenly in two patients and gradually in one, but the failure of respiration was not permanent. It was reestablished after ten minutes in one patient and after forty minutes in two. In none of these cases did respiration or circulation return to normal. The respiration was labored. The pulse rate varied from 120 to 160. The blood pressure dropped slightly in two patients but soon returned to normal. There was a marked elevation of temperature in all instances (from 105 to 108 F.). Convulsions, muscular twitchings and hypertonicity of the extremities and the trunk were present in all three cases. Death occurred after sixty, seventy-two and 119 hours, respectively. From the neurologic observations in the three fatal cases, the authors assume that death was due to the destruction of brain parenchyma. The two possible causes of this destruction may be asphyxia and the toxic effect of the gas. The asphyxia might be produced by anoxemia due to low oxygen content of the blood or to anoxemia due to collapse of the brain capillaries. Anoxemia due to oxygen deprivation should be relieved promptly by the administration of oxygen and is therefore not dangerous. Collapse of the capillaries associated with stasis and anoxemia as a responsible cause of degeneration of the parenchyma is suggested by the histologic picture, in that a definite selective destruction is noted, the cortex and the basal ganglions being much more severely damaged than the brain stem and the cerebellum, resulting in a clinical picture of decortification. Destruction of this type is frequently a toxic manifestation, and a similarity has been observed in cases of poisoning by excessive doses of pantopon (a mixture of opium and alkaloids) or/and morphine. Therefore, death may be due to extensive destruction of the cortex and basal ganglions rather than to involvement of the respiratory area alone.

**Splenectomy for Hemoclastic Crises.**—Curtis and his collaborators present the clinical evidence of eight patients in whom splenectomy was successful during an acute hemoclastic crisis. Six of the patients had congenital hemolytic icterus; two had thrombopenic purpura. The outcome supports the rationale of splenectomy in the treatment of properly selected and prepared patients suffering from hemolytic icterus or thrombopenic purpura of splenic origin. The authors attribute their success to careful differential diagnostic studies, optimal preoperative management and the application of modern surgical knowledge to the problem.

**Relief of Pain in Arterial Diseases of Lower Extremities.**—Smith treated forty-six cases of ulceration and gangrene in the lower extremities caused by occlusive arterial diseases by peripheral nerve block in the lower third of the leg. The operations were performed by exposing the nerves and blocking them with either injection of alcohol and crushing, division, or division and sutures or by crushing from 2 to 6 mm. of the nerve. Peripheral nerve block is an anatomic operation and should not be attempted until the operator has familiarized himself with the exact local anatomy. Poor wound healing may be attributed to extensive dissection because of lack of anatomic knowledge and failure to appreciate the amount of operative trauma these tissues will tolerate. Perfection of operative technic on anatomic specimens is recommended before the operation is attempted clinically. The procedure saved 50 per cent of the arteriosclerosis patients and 20 per cent of the arteriosclerotic with diabetes from a major amputation. No leg amputations were performed in the thrombo-angiitis group. The release of vasoconstriction by block increased the local temperature in the anesthetized area to varying degrees in the thrombo-angiitis cases, depending on the degree of arterial occlusion and spasm in the wall of the vessel. It made dressings, treatments, postural exercises, warm whirlpool baths, irrigation with diluted solution of sodium

hypochlorite, excision of sloughs and osteomyelitic sequestrums and drainage of local abscesses possible without subjecting the patient to multiple general anesthetics. Proper foot hygiene and shoes are necessary in order to prevent trophic ulceration in the insensitive member. Patients should be particularly warned not to expose the insensitive part to any form of heat. The relief of pain during wound healing has freed patients from sedatives, improved their appetites, increased their weight and permitted normal function of their gastro-intestinal and genito-urinary tracts which were interfered with by sedatives. Restful sleep has improved cerebral disorientation. Paralysis of the intrinsic muscles of the foot, which follows any type of nerve block, has not interfered with normal locomotion.

Syphilis: Review of Recent Literature. P. Padget and J. E. Moore, Baltimore.—p. 901.

**Postural Hypotension and Disease of Central Nervous System.**—Ellis and Haynes observed six patients with postural hypotension. In four there was definite evidence of neurologic disease (tabes dorsalis, syringomyelia and hematomyelia), and in an additional case there was some evidence of involvement of the central nervous system. The vascular responses were tested, and in two patients measurements of the circulatory dynamics were made. The total blood flow was found to be well maintained when the patient was in the erect position. Ephedrine was the most effective in relieving the symptoms. The effect of postural change on the blood pressure of patients with tabes dorsalis, combined system disease and miscellaneous neurologic lesions was studied. Ten of seventeen successive tabetic patients had an abnormal postural response of the blood pressure. Postural hypotension results from a failure of the normal sympathetic vasomotor reflex to produce vasoconstriction when the subject assumes an erect position. The center controlling this reflex lies in the brain and not in the spinal cord. Since the disturbance is widespread, the site of the lesion is either in a sympathetic center or in an afferent pathway controlling the entire response, or it is generalized throughout the efferent pathways or nerve endings. It is probable that multiple etiologic causes exist, but many instances of postural hypotension are associated with disease of the central nervous system.

**Nephrosis Following Transfusion with Incompatible Blood.**—Goldring and Graef point out that of about 2,000 transfusions performed during the last six years in the third medical and surgical divisions of Bellevue Hospital seven reactions of incompatibility occurred. There appeared to be no striking relationship between the amount of blood transfused and the severity of the reaction. Two patients who received 400 cc. died, whereas three patients who received 500 cc. recovered. Furthermore, a patient who received 200 cc. had a more severe and protracted course than one who received 500 cc. Three patients died, on the seventh, fourteenth and nineteenth days respectively. A prompt and marked diminution in the output of urine occurred in every instance. The longest duration of marked oliguria before the onset of diuresis and recovery was sixteen days. Slight but distinct icterus appeared in five of the seven patients and lasted for from five to fourteen days. When some urine was voided directly after the transfusion it invariably contained what was believed to

the start of the expiration until the breaking point is reached. After a rest period of at least five minutes the inspiratory phase is determined; a maximal inspiration is taken, followed at once by a maximal expiration, and the ensuing maximal inspiration is held, with compression of the nares as before. The duration is measured from the start of the final inspiration, since some persons fill their lungs more rapidly than others. The duration of the inspiratory phase is then placed over the duration of the expiratory phase and the fraction thus obtained expresses the duration of voluntary apnea. The arithmetical value of the fraction, that is, the index of stability, tends to approach a value of 1. Clinical improvement is accompanied by a reversion toward the normal range, from 1.8 to 2. Like many other methods of investigation of the deranged physiology of thyrotoxicosis, the estimation of duration of voluntary apnea is not necessary to the safe handling of only mildly hyperthyroid patients. But it is invaluable in making the decision between subtotal thyroidectomy and two stage operation for the severely thyrotoxic individual. After becoming thoroughly familiar with the use of the test, one need not expect to find a close, constant parallel between changes in the duration of voluntary apnea, pulse rate, basal metabolism, and the like, in the progress of a case. There is a general correlation in these and other criteria as the patient grows better or worse, but there is so obviously a selective mechanism at work in thyrotoxicosis, in that the chief expression of the disease varies among different organ systems from case to case, that the patient is rare who improves in all respects at the same rate. The various clinical criteria in thyrotoxicosis, to which the breath holding ability test is an addition, probably measure quite dissimilar facets of this many sided disease.

**Production of Vaginal Acidity by Estrogen.**—In view of the well known fact that, *in vitro*, the gonococci grow best in an alkaline medium and usually do not survive if it is rendered acid below a hydrogen ion concentration of 6, Lewis and Weinstein suggest that a change of reaction, to acid, of the vaginal secretions of children by treatment with estrogen similar to that found in monkeys might easily account for the destruction of the gonococci. In seventeen normal children, the youngest of whom was 4 months and the oldest 10 years, they found the vaginal secretions to have an average hydrogen ion concentration of 7.2. In ten children with gonococcal vaginitis, measurements of the vaginal acidity gave an average hydrogen ion concentration very near the neutral point. Eleven consecutive cases of vaginitis in which *Neisseria gonorrhoeae* was still present in smears and in which the vagina was found to have a hydrogen ion concentration of 6.2 or more were treated by inserting gelatin capsules containing 75 rat units of amniotin into the vagina at night, just before retiring. As a rule approximately two weeks of such treatment will result in a vaginal acidity of hydrogen ion concentration 6 or below. In no case (twenty-four in all) in which the vaginal secretions were found to have a hydrogen ion concentration of 6 or below for any length of time could the gonococci be found in the smear. The acidity of the vaginal secretions is in all likelihood the important factor concerned in doing away with gonococcal infections, when children so infected are treated with estrogen. Doederlein's organism was present in only a few of the children examined and its presence or absence could not be correlated with the acidity or alkalinity of the vaginal tract.

\*Interfering Agent in Human Blood Grouping. C. G. Ransom, Nashville.—p. 398.

**Interfering Agent in Human Blood Grouping.**—Ransom refers to an enzymatic agent that is often encountered but is frequently overlooked by the routine methods of blood grouping. The iso-agglutinogens being dominant mendelian characteristics and the finding of an interfering agent in several specimens of blood, which changed the groups, prompted

the investigation. The term iso-agglutinin is defined as being a substance in blood serum of an individual which has the power to agglutinate (or clump) the red blood cells of another individual belonging to the same species. While conducting a research problem with special regard to the blood groups, he encountered a most unusual phenomenon among six specimens of blood, all from different individuals of the same family and belonging to either group AB or B with parents of groups A and O. Stepchildren and illegitimacy were ruled out. Second specimens did not reveal the peculiar reaction but did disclose the bloods to belong to the groups that were possible for their parents to produce, such as A and O. Two of the first samples were preserved in the refrigerator, making it possible to correlate the first specimens with the second. Case 1 was found to be agglutinated by the standard serum A and failed to be agglutinated by the standard serum B; therefore, results of this test would place the person in group B. The second examination proved the blood to belong to group O. Case 2 was found to be agglutinated by the standard A and B serums. This person was considered to belong to group AB. These reactions took place at room temperature, although they could be greatly accelerated at lower temperatures. Cultures of the supernatant fluid from the first specimens of both cases disclosed a gram-negative bacillus which corresponds very closely to the description of Thomsen's B. He stated that this organism was an accentuating factor and would allow what he called an agglutinin (L) to act. The observations are not in entire agreement with those of Friedenreich, as only half of the bloods proved to be in false group AB and half in group B. Hence it may be concluded that the B typing serum was weak in agglutinin T, or L, as Thomsen named it. Although the serums possessed a strong titer for agglutinins A and B, it is not correct in the light of these experiments to consider this phenomenon as a panagglutination in all serums. Neither can it rightfully be called the normal cold-agglutinin, but it does seem plausible that these cells may have been sensitized by the enzyme, thereby allowing the cells to be agglutinated by the cold-agglutinin at a higher temperature. In order to overcome this particular source of error with the interfering agent, the blood must be examined within twelve hours after withdrawal if collected by the suspension method. The second method of detecting this phenomenon is by withdrawing the supernatant fluid from the suspicious cells and placing it in a refrigerator for twelve hours or longer with known O cells. If the cells agglutinate in any serum, the agent is acting. The third and best method is to test the cells in doubt with AB serum and, if agglutination takes place, the agent is acting and allowing the third agglutinin (L) to act on the red blood cells.

**Jaundice in Arthritis.**—In the last two years Borman has seen two patients suffering from a diffuse myofibrositis and periarthritis, whose pain was appreciably diminished with the development of jaundice. Neither patient had used alcohol prior to the development of jaundice. The reason for the analgesia and the mechanism of its action is not clear. Although an intense degree of jaundice was present in both patients and the degree of rheumatic pain from which they suffered was graded two plus on a basis of four, the analgesic action of jaundice, although definite, was incomplete. It continued, however, during the time the patients have been under observation.

than 1 cc. of insulin at any one site. Protamine insulin works successfully even if the carbohydrate in the diet varies from 100 to 275 Gm. The more complete control of the disease, which the new insulin makes possible, may so raise the standard of bodily health that the diabetic patient will be less subject to the various so-called diabetic complications and will resist them more successfully.

**Types of Diphtheria Bacillus in Illinois.**—Of the 162 strains of *Corynebacterium diphtheriae* that Grubb and Shaughnessy isolated from 109 cases and carriers, 5.5 per cent were grave, 78 per cent intermediate, 2.9 per cent mild and 4 per cent atypical strains, based on their colonial morphology on chocolate-tellurite agar. Two or more types of organisms were found in approximately 9 per cent of the cases and carriers. Repeated cultures from thirty cases and carriers showed that the original type was recovered at each of two, three, four or nine repeated examinations in 80 per cent of the cases and carriers. A change of type on repeated examination occurred in 20 per cent of the cases or carriers. Correlation of the type of organisms isolated with the clinical severity of the case indicated that the majority of the mild, moderately severe and severe cases were caused by the intermediate strains. Grave strains were not isolated in any of the severe or moderately severe cases. The percentage incidence of the grave, mild and intermediate types of the diphtheria bacillus may vary greatly in different localities. It also seems apparent that, where the prevailing type of diphtheria is mild in character, the incidence of the grave strain is low and it is not associated with severe cases of the disease.

**Hemophilic Pseudotumor.**—Firor and Woodhall cite the case of a hemophilic patient with a clotting time of from four to five hours, who presented an extraordinary instance of bone and joint involvement of the right thumb, in whom a roentgen

diagnosis of bone sarcoma was given on two separate occasions. However, the lesion represented the end result of hemophilic bleeding into a small articulation and into its adjacent osseous structure, as contrasted with the previously reported instances of similar disorders in large bones and joints. The pathologic sequence of events was similar to that taking place in large bones and joints, but instead of regression and eventual ankylosis in the small bones and joints there may be also progressive destruction and cutaneous rupture. The roentgen diagnosis of hemophilic bone and joint lesions must be qualified in the future by these anatomic differences. Amputation of the pseudotumor was successfully accomplished with the electrocautery, and postoperative healing was essentially normal. This technic, with the supplementary aid of blood transfusions, appears to offer a distinct advance in the surgery of the patient with hemophilia. The favorable influence of cauterization of hemophilic tissue on reduction of the clotting time has been suggested by the observations in the case and is being studied further.

**Heterophile Antibodies in Infectious Mononucleosis.**—Beer made a study of the heterophile antibodies in serums from normal persons, from patients with infectious mononucleosis and from individuals who have received injections of serum. He found that in infectious mononucleosis the antigen with which the so-called heterophile antibodies react is found in horse, goat, sheep and beef blood corpuscles. The agglutinins for the blood corpuscles of sheep, horse and goat are markedly increased. In the case of beef blood corpuscles the hemolysins are increased but the agglutinins are not. Each of these kinds of blood corpuscles can absorb almost completely the agglutinins for the blood cells of each of these species. On the other hand, these antibodies are almost non-absorbable by any antigen for which the corresponding agglutinins are not increased. After injection of serum, the increased agglutinins for many kinds of mammalian blood corpuscles show about the same sequence in their titer as is found in serums of persons without a history of injections of serum. Serum from patients with infectious mononucleosis can be differentiated from normal serums and from those obtained after the injection of serum by absorption of the sheep, horse and goat agglutinins with sheep, beef, horse and goat blood corpuscles or by the resistance of these increased agglutinins to absorption by any of the blood corpuscles the agglutinins for which

**Biologic Method for Control of Dracontiasis.**—Moorthy and Sweet point out that the following six species of small fish were found to be of use in guinea-worm control: *Barbus (Puntius) puckelli*, *Barbus (Puntius) ticto*, *Lepidocephalocythus thermalis*, *Rasbora doniconius*, *Barbus sophore* and *Barbus chola*. To these fish have since been added a species of *Gambusia*, imported from Italy, which has also been found useful. All these species of fish feed on such copepods as cyclops, daphnia, cypris and diaptomus, under both laboratory and field conditions, although *Barbus puckelli* and *Barbus ticto* are the most active in this respect. Any species of fish to be useful in dracontiasis control should feed on and digest copepods, especially cyclops, should be a prolific breeder and should have its breeding season just before or coincident with the guinea-worm transmission season. Since 1934 fish have been introduced into step-wells in thirty-five infected villages, with the result that guinea-worm disease has disappeared in six and been markedly reduced in four. In certain of these villages the fish have not survived. Investigation has shown that this may be due to the bailing out of water to remove silt, to the drying up of the well in summer, to unexpected chemical treatment or to the catching of the fish for eating when the water is low. It is also probably true that certain waters because of their chemical or biologic peculiarities will not support these fish. The abolition of step-wells is the only permanent and fool-proof measure for the control of this disease.

**Experimental Transmission to Man of *Treponema Pertenu*.**—Lamborn outlines the habits of the hematophagous group of Muscid flies, as typified by *Musca sorbens*, the commonest representative in East Africa, which suggest the likelihood of their especial responsibility for the dissemination of pathogenic organisms present in skin lesions. A study of the precise manner in which such infections could be spread by the fly was carried out, with regard to *Bacillus leprae*, in the first place. It was then ascertained that, after regurgitation has taken place from an infecting meal and the vomit drop has been withdrawn, these organisms may be laid down on whatever food material to which the insect may happen to apply its

proboscis shortly afterward. *Bacillus leprae* may be deposited up to twenty-four hours from the infecting meal. It was further ascertained, as a result of the observation, that a trypanosome, *Trypanosoma rhodesiense*, also may be deposited by the fly, and in viable condition up to half an hour. It has been proved conclusively that this fly must play a very definite part in the transmission of yaws as a result of its habit. The chance fall either of the excreta or of the vomit drop in the right situation plays a minor part in producing such infection compared with this definite purposeful act on the part of the fly. Full data on the transmission of the causative organism from one human subject to another by the fly are given.

**Storage of Cystine.**—Russell and Barrie cite three cases in which advanced chronic interstitial nephritis was associated with a disturbance of cystine metabolism. In two instances cystine was stored in the reticulo-endothelial system, the deposits being visible to the naked eye as opaque ochraceous flecks and streaks. In the third, cystinuria and stone formation were recognized in early childhood; no cystine was found in the tissues at necropsy. Only four cases are on record with a similar storage in the tissues. In none of the six cases in which storage of cystine in the tissues has been found at necropsy had cystinuria been established clinically before death. The association of underdevelopment and rickets with a disturbance of cystine metabolism in Lignac's three cases and in one of the authors' cases raises the question of the nature of the relationship of these conditions. A disorder in which the metabolism of this substance is impaired might well be accompanied by a retardation of growth. Yet underdevelopment is not a recognized feature of cystinuric subjects, being intermittent in cystinuric children. Likewise the association of rickets with cystinuria is shown by the same cases to be inconstant. Yet the identification of a disturbance of cystine metabolism combined with rickets in Lignac's cases and in one of the present cases suggests that the association cannot be dismissed as coincidental. Lignac's experience suggests that cystine storage would be found much more often in rickets, or in any rate renal rickets, if the possibility of its presence were kept in mind and steps taken for its detection. There are clinical considerations which suggest that the cystine diathesis may not be excessively rare in renal rickets as a class. The occasional record of glycosuria in renal rickets recalls the report of pentosuria, and later slight glycosuria in one of Lignac's cases and of glycosuria in the authors' case. The familial occurrence not only of cystinuria but of renal rickets and the not uncommon record of calculi of unspecified chemical composition in the urinary tract in cases of renal rickets and infantilism again suggest the linkage of faulty skeletal growth with cystinuria. It appears likely that renal rickets rests on a basis of renal injury, whether this is due to chronic interstitial nephritis or to nephritis consequent on demonstrable obstruction in some part of the urinary tract, or on dilatation indicated solely by dilatation and hypertrophy of the urinary tract. The similarity in the nephritis found in the authors' three cases raises the question whether the continual excretion of cystine in the urine may give rise to chronic nephritis and hence, in some instances at any rate, to renal rickets. There is experimental evidence, from the oral administration of cystine to rats and rabbits, that the kidneys are damaged thereby. The suggestion that the kidneys of young growing animals are more susceptible to this kind of injury than are the kidneys of adults agrees with the data so far available in the human species.

vascular obstruction of the ureter in children treated surgically. The youngest patient was 14 months old. He finds that vascular compression of the ureter is not uncommon in children. Vessels that produce the obstruction are congenitally anomalous. Hydronephrosis is the important uropathy and is usually infected. Pain in the renal region, pyuria, hematuria, a mass in the loin and, with the advent of infection, fever are the commonest symptoms. Most children with vascular obstruction of the ureter are treated for months for chronic pyelitis. In the absence of infection the renal changes as interpreted by urinalysis regularly cause the diagnosis of chronic interstitial nephritis to be made. Yet the correct diagnosis can usually be made preoperatively by a complete urologic examination. The probable diagnosis is often suggested by excretory urographic observations. Delayed diagnosis and radical surgical treatment are usually reciprocal. Conservative surgical treatment may be expected to save a gratifying number of injured kidneys. Unfortunately the medical profession is as yet insufficiently alert to the high incidence and importance of urologic disease in children. Because of the consequent delay in making the diagnosis, nephrectomy will necessarily be the treatment in fully half of all children with vascular ureteral blockage.

**Operations for Relief of Incontinence.**—His new operation for impotence, in which Lowsley uses three figure-of-eight ribbon-gut stitches to tighten the bulbocavernosus muscle in the male, has resulted in the inability of many patients to void. One patient, who was both impotent and incontinent, was entirely cured of both conditions by the operation. This accidental result prompted the use of the method in certain cases of incontinence. The patient is placed in the lithotomy position and a 20 French sound is inserted into the urethra. A median or Y shaped incision is made in the perineum and deepened through fat and Colles fascia, exposing the bulbocavernosus muscle, which is then dissected free on its sides. Chronic ribbon gut, studded with an atraumatic needle, is inserted well down on the lateral surface of the muscle. It is then fixed in a similar manner on the opposite side, pulled tightly across the posterior surface, and tied in a square knot. This is repeated at two other points over the bulbocavernosus muscle, resulting in a rather firm plication of the entire muscle. The sound is removed and the fascia and skin are closed with plain catgut and fixation sutures, respectively. It is usually necessary to catheterize the patient every eight hours for two or three days after the operation. In cases of preexisting incontinence, the patient is instructed to void every two or three hours while up and about and to use suprapubic pressure if necessary. The choice of operation for incontinence in the woman depends on the situation. If the urethra is very large and patulous and the patient is entirely incontinent, the ventral surface of the urethra is plicated. If, on the other hand, the patient merely loses a few drops of urine on coughing or other violent muscular activity, encircling the urethra with a piece of ribbon gut and tying it snugly will be all that is necessary to effect a cure. Operations were performed in thirty-five cases of incontinence; six of these were reported previously. The ages of the twenty-nine patients varied from 4 to 66 years. Twenty were women. The operations performed on the women were: suprapubic cystostomy with plastic repair of the vesical orifice, and the roof of the urethra, eight cases; Kelly urethroplasty, four cases, and Lowsley urethroplasty with ribbon gut, eight cases. The operations performed on the nine males were: suprapubic cystostomy and plastic repair of the vesical orifice, six cases, and perineal plication with ribbon gut, three cases. The operative result was favorable in all but four cases. These patients had to be reoperated on, one of them three times.

**Allergic Shock.**—Pierson warns that the frequency of severe reactions following such usually innocuous procedures as skin testing by the scratch method, the injection of diphtheria toxoid or the taking of certain drugs, as antipyrine, is not generally appreciated. Waldbott has reported a series of such reactions. To these the author adds brief summaries of six such cases seen in private practice. Scratch testing, the injection of diphtheria toxoid, the giving of prescriptions containing such drugs as ipecac, antipyrine, aminopyrine and phenolphthalein or the employment of home remedies such as mustard by mouth or in a plaster should not be undertaken without a knowledge of the family allergic background and the child's previous history. Especially should one be careful in scratch or intradermal tests with such atopens as egg, cottonseed or kapok seed, buckwheat, horse dander, fish glue and mustard.

**Small Corpuscle in Chronic Leukemic Blood.**—Fiessinger and Laur describe a small corpuscle that can be found in the blood in certain leukemic patients. In smears stained by the May-Grünwald method it appears as a small body most often regularly round, colored a pale blue like the cellular cytoplasm and without any trace of azurophilic chromatic particles. Its dimensions are between 4 and 8 microns. It is usually smaller than an erythrocyte. It is found in the microscopic field at about a ratio of 1:500 or 1:1,000 red cells. It appears in the form of a homogeneous disk, more refractile than the blood cells but less brilliant than the platelets. The nature of this body is considered from the standpoint of the circumstances of its appearance and the conditions that lead to its formation. It cannot be found in the blood in early leukemia. It is seen in chronic lymphatic leukemia and chronic myeloid leukemia relatively late in the course of the disease, and generally it is contemporary with the period of radioresistance, which fact seems to possess a serious prognostic significance. Its appearance in the circulating blood seems to be related to the presence of indifferent cells and affected by certain technical conditions. The circumstances of appearance of these corpuscles direct investigation toward the conditions of their formation. It is incontestable that this terminal radioresistant phase of the leukemia corresponds to a multiplication in the circulating blood of embryonal cells. Thus the effect of the cytoplasmic fragility of the embryonal cells produces either by direct bleeding, by direct aspiration into the pipet or in making the smear a localized segmentation of the cytoplasmic portion of the cell. This results in a "lost body," which is the corpuscle discussed. Hence, they believe that the cell is an artefact; nevertheless, consideration of the special conditions that lead to its formation possesses value as a test of leukocytic fragility, and this explains its prognostic gravity.

**Diagnosis of Cancer of Esophagus.**—Soulas reports the study of ten patients with regard to the early diagnosis of cancer of the esophagus and concludes that the irrefutable diagnosis of cancer of the esophagus and its histologic type can be established only by biopsy and histologic examination. Biopsy is sometimes impossible in the early phase, especially in submucous cancer and in the cervical location. Strictly speaking, this importance of the biopsy cannot be compensated for by other signs. Thus there are disorders which are harmless but which may give signs and symptoms characteristic of those classically believed to represent cancer of the esophagus. Nevertheless the early recognition of dysphagia must suggest cancer in an early phase and has a presumptive diagnosis which may later be confirmed by biopsy. In cancer of the cervical esophagus, this presumptive diagnosis may become a sufficient indication for exploration or treatment.

**Tubercle Bacilli in Stool Cultures.**—Progress in recent years in developing satisfactory methods of culturing tubercle bacilli led Bezançon and his colleagues to investigate the pos-

sible value of taking cultures of the stools for these organisms. Their investigations were made on 231 specimens of stools. In 174 of these it was not possible to find acid-resisting bacteria either by direct examination or by cultures. Thirty-five of these constituted merely a simple control for verification of the value of the method. In nine, definite pulmonary tuberculosis was present but examination of the sputum had not demonstrated the bacilli. They believe that cultures of the stools, if not exposed to causes of possible error and if kept in a practical form, can be used as a laboratory analysis comparable to cultures of the sputum but may give positive results when the latter are negative.

**Prognosis of Cirrhosis of Liver.**—According to Chabrol and Sallet, the uncertainty of the late prognosis of cirrhosis of the liver necessitates study. With this in mind they attempted to use the quantity of polypeptides in the blood as a prognostic index. The method of Goiffon and Spay was used for determining the polypeptides, and the phosphovanilla method for measuring the cholic acid of the blood. Their investigations concerned 300 patients, of whom 124 had cirrhosis. With this method of measuring polypeptides, a level of 21 mg. could serve as the dividing line of prognostic classification. When above 21 mg., the evolution is favorable in 75 per cent; when below this level, it is fatal in 70 per cent. Parallel examinations of the cholesterol and cholic acid of the blood were made in 111 cirrhotic patients. When the level of blood cholesterol fell below 1.2 Gm. per thousand, the prognosis was unfavorable in almost all. Inversely, when the level was above 2 Gm. per thousand, the prognosis was good in 88 per cent of the cases. These observations, the authors hope, will aid considerably in forming a satisfactory opinion as to the late prognosis in cases of cirrhosis.

**Primary Mammary Cancers in Axilla.**—Matti points out that the ectopic mammary tumors deserve attention because their diagnosis may cause considerable difficulties. He reports a case in which the previous history caused an erroneous diagnosis. Two decades previously the patient had been operated on for tuberculosis of the cervical glands; therefore a gradually increasing swelling in the left axilla was at first diagnosed as tuberculosis of the lymph nodes. Treatment with roentgen rays considerably decreased the glandular swelling in the axilla, but later there was a renewed enlargement. A progressive change in the skin finally suggested the possibility of a neoplasm, and an exploratory excision revealed a mammary carcinoma with metastases in the axillary lymph nodes. However, careful palpation of the left breast gave no indication of its involvement. Following removal of the mammary carcinoma from the axilla, changes appeared in the breast but seemingly had no connection with the axilla. Nevertheless, amputation of the breast became necessary. The author emphasizes that this and other cases indicate that in cases of axillary mammary carcinoma the breast is likewise threatened and should be removed together with the axillary carcinoma even though palpation fails to reveal involvement.

will slow the growth in case of incomplete surgical removal or inaccessibility. The spongioblastoma polare is slow growing and situated in the cerebral axis and brain stem. It is the most common form of glioma found involving the optic chiasm and is frequently associated with von Recklinghausen's disease. If calcification is seen in a position close to the clivus and obviously in the pons with or without evidence of increased intracranial pressure, if the patient is young and the history long and slowly progressive, a diagnosis of spongioblastoma would be highly probable. Roentgen therapy is often the only form of treatment, as the growths are surgically inaccessible. The ependymomas occur as ependymoma and ependymoblastoma. The ependymomas often occur in children and frequently calcify sufficiently to cast a shadow in the roentgenogram. Calcification, if present, will usually be found as a small flocculent amorphous deposit near the midline in the posterior fossa or possibly near the position occupied by the lateral ventricles. Operation should be resorted to, followed by intensive irradiation to forestall a recurrence. The roentgen diagnosis of a pineal tumor is usually difficult without air studies. Roentgen therapy or surgical intervention has little to offer. Papillomas of the choroid plexus are rarely encountered in patients more than 10 years of age and their site of election is the fourth ventricle. The diagnosis is aided by air studies. The shadow cast by calcification in a large glomus of the choroid plexus should not be confused with a papilloma. In a large percentage of benign choroidal calcifications they are bilateral, but papillomas have been found simultaneously in the two lateral ventricles. The tumors are vascular and irradiation has been known to reduce the vascularity and the rate of growth.

**Air in Hepatic Ducts as Roentgen Sign of Biliary Fistula.**—Powers believes that air in the bile ducts must be a common observation, as it was present in three of the four cases observed by him. Air shadows are usually tubular or branched, and follow the general direction of the common duct. Air may surround a calculus in the gallbladder and cause a crescentic shadow. On two occasions he has observed tubular transparent shadows arising near the spine and extending downward from left to right. He can find no adequate explanation of these pseudo air shadows. They may be due to fat in the ligamentum teres hepatis. One of the patients was operated on for a perforating duodenal ulcer and no fistula was present. Air or barium rarely enters the hepatic ducts except through a biliary fistula. Not infrequently one sees the opening of the ampulla outlined bluntly, but barium is never seen to enter the duct. In case of a recently passed gallstone or malignant infiltration, the ampulla may be gaping open. He has found no previous mention of a solitary faceted gallbladder calculus being the basis for a diagnosis of biliary fistula. Such a diagnosis appears almost fool proof, but it is possible that one stone might have a high calcium content and the other be almost pure cholesterol. In the case that he describes there was a minimum of calcium in the missing stone. In cases of intestinal obstruction, careful search should always be made for air shadows.

**Calcified Mesenteric Lymph Nodes.**—Schechter found calcified mesenteric lymph nodes in 1.7 per cent of 2,119 routine gastro-intestinal roentgen surveys. Comparative incidence observations are 1.9 per cent in 1,000 consecutive cases of lumbosacral spine roentgenograms and 2.8 per cent in 1,000 consecutive roentgen examinations of the urinary tract. In 60 per cent of the cases the site of the calcified nodes was the right lower quadrant of the abdomen. An increased percentage incidence of both local and general symptoms is noted, but a relation to calcified lymph nodes is not apparent. In 80 per cent of the cases in the series, abdominal pain and tenderness was absent or these symptoms were localized at sites other than that of the calcified nodes. Of this number, 28.5 per cent had no abdominal pain or tenderness. Abdominal pain and tenderness, which are considered prominent symptoms in the clinical evidence of calcified mesenteric lymph nodes, do not appear to bear this symptom relationship when these nodes are found in routine roentgen studies of the gastro-intestinal tract. The relationship to the general symptoms of nausea and vomiting is also indefinite.

**Obstructive Jaundice.**—A method is presented which, Foote and Carr believe, will reduce the percentage error in differentiating operative from nonoperative cases. It is a modification of the Graham-Cole roentgen technic and is dependent on the fact that, even though the common bile duct has been completely blocked, dye will still be excreted by the liver and concentrated in the gallbladder, where it will remain visible by x-rays for several days. Dye (iodelikon, intravenously in divided doses, from 250 to 750 mg., with dextrose) was given to seventeen patients suffering from well developed jaundice, twelve of whom were blocked completely. The dye held in the gallbladder over a long period is often unevenly distributed or gathered in pools, giving a false appearance of stones. It also may settle to the tip of the fundus, giving a dense, semilunar shadow if the patient has remained quietly in bed. On the other hand, the dye given to patients with jaundice due to intrahepatic obstruction fails to visualize the biliary system in a single case after forty-eight hours. Although normal shadows of the gallbladder may be seen at twenty hours, the gallbladder empties at forty-eight hours and no shadow is cast. Two of three such patients with clinical pictures of common duct stone proved at operation to have catarrhal jaundice. The gallbladder and bile ducts were normal. The diagnosis without the x-rays is uncertain in many cases of jaundice in spite of the fact that full hospital and laboratory facilities are at hand but may be made by this method in some instances. With their present meager experience with this method, the authors feel that it offers an effective means of differentiating intrahepatic from extrahepatic biliary obstruction in most cases. When such tests give positive evidence, operation is not advised.

**Duration of Voluntary Apnea in Thyrotoxicosis.**—Bartlett confirms the previous observation that in thyrotoxicosis there occur (1) a decrease in the duration of the apneic interval in inspiratory and expiratory phases and (2) a characteristic alteration of the relationship between their numerical values and a return toward normal values as the patient improves and achieves sufficient stability to withstand operation. The test is performed under basal conditions. The duration of the apneic interval after expiration is usually made first. A maximal inspiration is taken, followed immediately by a maximal expiration and the nares are lightly compressed by the examiner's fingers; the duration is counted with the watch from

and pustules. It is characterized by a moldlike pseudomembranous coating, superficial ulceration and pyofibrinoid infiltration of the epithelial and subepithelial layers of the mucous membrane. More serious lesions are not observable. The glycogen of the vaginal epithelium is greatly reduced. The trichomonas organism lives only in the cast-off, necrotic tissue detritus, for it could not be found in the intact tissues. The vaginal flora and the vaginal chemistry (lactic acid content and hydrogen ion concentration) are not noticeably influenced by the parasite. It lives in symbiosis with the Doederlein bacillus and it produces lactic acid. This explains the comparatively slight pathogenic significance and the fact that it is denied by many. The irritation of the vaginal wall and the leukorrhea are the results of the irritative action of the protozoon. The development of pathologic changes and their degree is dependent on the virulence of the parasite and on factors in the patient's organism. Although Trichomonas prepares the way for the entrance of pyogenic cocci, it inhibits their virulence by the production of lactic acid. In the puerperal morbidity, Trichomonas plays no important part.

**Menstrual Cycles and Physical Exercises.**—Škerlj analyzed the menstrual records of young women attending a school for gymnastics. In some of the young women the period of observation covered twenty-one or twenty-two months, in others only half that time. Dysmenorrheas were comparatively frequent and in some of the cases their appearance indicated a connection with bathing and swimming in cold water. Amenorrheas seemed to be more frequent during the cold period, but apparently there was a connection with the skiing courses, whereas camping trips in the summer time seemed to have no such influence. Only 20 per cent of the women showed no changes in their menstrual cycles, whereas the remaining 80 per cent showed temporary or "constant" changes. The author thinks that this high incidence proves a direct connection between the changes in the menstrual cycle and the intensive physical exercises. He advocates the prohibition of intensive training and of athletic contests and advises against all forms of heavy gymnastics during the menstrual period, emphasizing that the possibility that the menstrual changes produced by intensive physical exercises are only temporary and do not cause permanent damage should not change this attitude.

### Deutsche medizinische Wochenschrift, Leipzig

62: 1905-1944 (Nov. 20) 1936. Partial Index

- Detachment of Spinous Process. E. Metge.—p. 1922.

**Studies on Accelerated Development.**—Koch directs attention to the fact that measurements during recent years have revealed an increase in the height of children. Moreover, the second dentition, the change of voice and particularly the menarche occur earlier. However, the author maintains that the average size of adults has not noticeably increased in recent years and so he concludes that not so much the external appearance as the course of the development of man has undergone a considerable modification. He cites another investigator who made practically the same observations; namely, that in spite of the considerable increase in the size of young persons the average size of adults is not increased, because of a compensatory shortening of the duration of growth. The author further discusses the factors responsible for the accelerated growth and then describes animal experiments on this problem. By various diets and by additional ultraviolet irradiations, great differences in the lengths of various groups of rats were achieved. The experiences were interrupted on the same day; that is, when the animals were of the same chronological age. The ovaries of the animals were cut in sections and the primordial follicles were counted, for it is known that young females have more and old females have fewer primordial follicles. It was found that the number of follicles was in inverse ratio to the rapidity of growth. From this the conclusion was drawn that, although all the animals were of the same chronological age, those with

the smaller number of follicles were "biologically older" and those with the greater number of follicles were "biologically younger." Thus it seems that an accelerated growth corresponds to a premature aging process.

**Dietetic Treatment of Neurodermatitis.**—Mulzer and Sörensen-Petersen emphasize that the regulation of the diet is one of the most important factors in the treatment of neurodermatitis and that a restriction of sodium chloride and its replacement by some other type of salt is of primary importance. They show that, in contradistinction to the local treatment, the diet is to a certain extent a causal measure and prepares the way for an effective local therapy. The latter should supply fat for the usually dry skin. The itching is often effectively counteracted by tamenol or by tar preparations.

**Lymphatic Reaction and Encephalomeningitis.**—Sucher and Schwarz direct attention to meningo-encephalitic complications in infectious diseases, pointing out that, if the symptoms of the primary infectious disease are fully and clearly developed the diagnosis is not difficult but that the appearance of the cerebral symptoms during the first stage may mask the primary disorder. The authors describe the history of a girl, aged 15, who two years previously had had a mild tuberculous process in the pulmonary apex. She suddenly became ill with fever, headache, glandular swellings, splenic tumor and symptoms of meningeal and encephalic irritation. The examination of the blood disclosed a severe lymphoblastic-plasmacytic reaction with simultaneous deviation to the left of the neutrophilic leukocytes. Roentgenoscopy of the lungs revealed swellings of the lymph nodes at the hilus and a few small spots in the subclavicular region of the lung, which suggested the possibility of a hematogenic dissemination and of the tuberculous nature of the meningeal disorder. However, a blood culture according to Löwenstein remained sterile and all the symptoms disappeared in a comparatively short time. But ten days later the swellings of the lymph nodes of the spleen and of the liver and the high fever recurred. The changes in the blood were even more pronounced than in the beginning. Four days later the symptoms of the central nervous system recurred and severe convulsions developed. After seven hours of an epileptiform condition a pulmonary edema developed and the patient seemed to be in an agonal state. Spinal puncture disclosed high pressure, increased protein content and a considerable number of lymphatic cells in the spinal fluid. Gradually the symptoms as well as the blood changes disappeared and the patient recovered. The authors point out that this case is an example of a so-called metastatic encephalomeningitis which completely masked the nature of the acute infectious disease. They show that such cerebral complications are most frequent in those infectious diseases the pathogenic agents of which are not as yet completely understood and which probably take a special position in the microbiologic system. To this group belong measles, chickenpox, whooping cough and epidemic parotitis. Opinions are still divided regarding the relationship between the primary infectious disease and the cerebral complications. The authors give their attention chiefly to the changes in the blood and reach the conclusion that this case represents an encephalomeningitic complication of Pfeiffer's glandular fever. They also succeeded in detecting certain pathogenic relations between primary disorder and the cerebral symptoms to the effect that the virus of the glandular fever is responsible also for the inflammatory disorder in the central nervous system; that is, the condition is a true metastatic encephalomeningitis.

**Pathogenesis of Diaphragmatic Relaxation.**—Schumann reports the clinical history of a man whose symptoms resembled those of a sinistral pleurisy. However, roentgenoscopy revealed a diaphragmatic relaxation. The author mentions the most important symptoms of diaphragmatic relaxation and stresses

**Minor Cord Lesions and Injuries of Cervical Spine.**—Walshe and Ross deal with injuries in which the spinal cord loses sustain some relatively slight damage, either a momentary tipping when there is displacement of cervical vertebrae in relation to one another, or a momentary stretching over the posterior aspect of the vertebral bodies when the head is forcibly flexed, as in a fall in which the vertex strikes the ground first. Of the six cases which form the material of the present study, only one had been recognized, though more than one had been submitted to neurologic examination. The diagnoses actually made included progressive muscular atrophy, myotrophic lateral sclerosis, primary lateral sclerosis and arthritis of the shoulder. It is the history of injury which is in a measure responsible for directing attention away from the cervical spine and cord, since it is the head which first receives the violence and not the neck. The common story given by the patients is that, when the resumption of activity begins after recovery from the immediate effects (e. g., concussion) of the injury, they find the arms alone or both arms and legs weak. This weakness may persist unchanged, may gradually and partially clear up, or may even slowly increase with the passage of time. In the authors' experience it cannot be assumed that the relatively moderate degree of the initial disability means that complete recovery may be looked for within a short or measurable period. The appearance of muscular wasting in the upper limbs is not invariable, and when it occurs it may not be noticed by the patient for some weeks. The essential elements in the clinical picture are: (1) limitation of movement of the head and neck, with pain and stiffness on movement; (2) some general weakness of the upper limbs, sometimes associated with special weakness and wasting of muscles supplied by the fifth and sixth cervical segments; (3) characteristic differential changes in the tendon jerks in the arms, usually including inversion of the radial reflex; (4) slight hypertonus of the extensor group in the legs, with increased knee and ankle jerks, and in some cases ankle clonus and extensor plantar responses; (5) an absence of sensory loss; (6) absence of defects of sphincter control, and (7) slow and imperfect recovery.

**Tumors in Ventral Aspect of Pons and Medulla.**—Stevenson and Friedman present two cases of tumor at the base of the brain and two cases of chordoma, a tumor derived from the remains of the notochord. Chordomas may grow from either end of the remains of the notochord. The growths are usually not malignant but, if removed surgically, tend to recur. Occasionally they give rise to metastases in other parts of the body. One cannot establish a definite syndrome for tumors located in this region, but the authors believe now that signs of involvement of one or both hypoglossal nerves, or others of the lower cranial nerves, might help to place the tumor in front of the pons and medulla rather than in the fourth ventricle. Moreover, these tumors differ in several important respects from tumors invading the pons (e. g., glioma), from acoustic neuromas and from tumors of the fourth ventricle. Tumors of the fourth ventricle itself usually give rise to the von Bruns sign (sudden vertigo with change in

posture), signs of internal hydrocephalus with perhaps evidence of distant pressure on the chiasm owing to herniation of the floor of the third ventricle. These cases, as a rule, are characterized by the absence of cranial nerve phenomena. Many of the tumors at the base are latent and symptomless, but they may involve any of the lower cranial nerves from the eighth to the twelfth. They are frequently accompanied by disturbances in respiration and heart rate and by the presence of intermittent glycosuria. Some of the more characteristic signs and symptoms include occipital headache, attitudinizing of the head, cerebellar ataxia and an intermittent course. Syphilitic meningitis at the base might enter into the differential diagnosis, but it is more apt to give rise to the picture of an angle lesion. Vascular lesions of the pons and medulla are apt to give rise to more definite and clearly defined syndromes, involving the distribution of the superior cerebellar artery, the posterior inferior cerebellar artery, the vertebral artery or the basilar artery with its branches.

**Physical Deformities and Rickets.**—Pritchard believes that, according to the more modern acceptance of the term "rickets," this appellation should properly be confined to the group of symptoms which are directly attributable to a deficiency of vitamin D and are due to a failure in the fixation of calcium in growing bone. Not all bony deformities, however, are the result of deficiency of vitamin D. Many are of a congenital nature, and others are due to the mechanical effects of laxity of ligaments and muscular weakness. Many of the common deformities, such as flatfoot, knock knee, bandy legs, lordosis, kyphosis and pigeon chest, the sort of deformities which most frequently come under the notice of the pediatric physician and which are generally described as "rickety deformities," are clearly not due to this cause. Flatfoot is generally due to laxity of ligaments, muscular atony and an excessive bodily weight due to overfeeding, imposed on the arches before they are in a condition to withstand the strain. Knock knee is due to very much the same causes, with the additional factor of straddling of the legs, owing to difficulties which the child experiences in maintaining equilibrium when it begins to walk. Bandy legs generally represent the persistence of the intra-uterine tibial curvature, which is caused by the crossing of the legs on the abdomen in a cramped position. Mentally defective, degenerate and otherwise debilitated infants remain inactive, and the legs continue in the uterine position, and consequently the curves are not obliterated and when the child begins to walk there is a tendency for the tibial curves to be exaggerated. Most varieties of spinal curvature are due to muscular atony and laxity of the ligaments, with resulting faults in posture. Pigeon chest is seldom traceable to a true rickety origin; although due to mechanical causes, there is nearly always some congenital or familial element in the pathogenesis. Faulty methods of feeding, with various deficiencies and excesses, are generally discoverable. Wrong methods of breathing, excessive coughing and respiratory obstruction may play a part in the pathogenesis. The so-called rickety deformities, like many others of the reputed symptoms and signs of rickets, are really due to one or the other of the many combinations of deficiencies and excesses that may occur in any maladjusted dietary, and the cure for them is not the specific treatment for rickets but the correction of the primary cause.

- \*Surgical Treatment of Pulmonary Tuberculosis. J. Holst.—p. 1211.

**Anemia in Patients with Tuberculosis.**—Rasmussen says that of 460 patients with pulmonary tuberculosis 12 per cent had anemia, and of the 343 with positive tubercle bacilli in the sputum, 15 per cent. There was no difference between the kind or extent of the tuberculous process in the 409 non-anemic and the fifty-seven anemic patients and there is little evidence that the tuberculous process in itself has a deleterious effect on erythropoiesis. Treatment with iron resulted in recovery from the anemia in 60 per cent of the cases. The reaction to iron, together with the frequency of achlorhydria or hypochlorhydria, indicates a disturbance in the iron metabolism. In thirteen cases the anemia depended on spread of the tuberculosis to other organs, particularly intestinal tuberculosis with diarrhea. In ten cases the anemia was due partly to complications, partly to unknown causes. Since the majority of the anemias in pulmonary tuberculosis respond to iron therapy, systematic hemoglobin examinations and treatment of the anemias with iron seem to be of importance in the treatment of pulmonary tuberculosis.

**Total Thoracoplasty in Pulmonary Tuberculosis.**—Gjessing reports the results in ninety-seven cases of total and subtotal thoracoplasty. The operative mortality was 9.3 per cent. He says that the indication for this intervention includes patients for whom it is a last resort. It offers the patient about a 45 per cent chance of becoming capable of working and free from symptoms and about a 75 per cent chance of improvement with ability to work for a longer or shorter time, while the chance of unchanged condition or fatal outcome is about 25 per cent. He believes that improved results may be obtained by (1) operation in a quiescent phase of the disturbance and adequate observation after operation, calling for extension of the cooperation between surgeon and internist, and (2) timely collapse treatment in men with pulmonary tuberculosis on the right side, so that the intervention may be as small as possible, as the highest mortality occurred after thoracoplasty in one session of treatment in these cases. Further, while the technical performance of total thoracoplasty is usually not difficult and rarely the determining factor in the operative mortality, it does affect the degree of collapse produced. Extirpation of the upper ribs, together with exarticulation of the ribs in the costovertebral joint in cases of larger cavities at the top of the lung, is a technical advance.

**Partial Thoracoplasty in Pulmonary Tuberculosis.**—Semb's material consists of 147 cases of thoracoplasty with extrafascial apicolysis, with ten deaths within two months. Examination of ninety-nine patients after from one to three and three-fourths years shows sixty-seven free from bacilli and fifty-nine wholly or partly capable of working. One of the advantages of the method is access to collapse of the other lung. Particularly individualized treatment in short sessions have been given in forty-five cases during the last year and a half, with one death within two months, or 2 per cent mortality, and with complete collapse of the cavity for the time being and freedom from bacilli in forty-two cases.

**Surgical Treatment of Tuberculosis.**—Holst's principle is radical resection of the upper ribs, plastic operation of the soft tissues, consisting in division of the periosteum and soft tissues of the upper ribs, and a radical apicolysis. A flap of periosteum is produced which forms a lid over the collapsed lung apex. In this position the ribs are regenerated. The large wound cavity over the apex of the lung is filled with exudate and air. This wound cavity pneumothorax and the exudate press together the pulmonary apex, the wound cavity

exudate acting as a natural filling. It is resorbed after two or three months. The material comprises ninety-two cases in which operation was performed according to the technic described, with two deaths, and 157 cases, including more unfavorable cases than the first group, in which operation was done by other methods, with about 8 per cent mortality. The author states that in uniform cases the mortality rate is probably not higher in Semb's extrafascial modification of apicolysis than with the technic here presented.

**So-Called Recurrence of Scarlet Fever.**—Thirty cases of recurrence of scarlet fever in hospitalized children during the last two and a half years are reported. The cases occurred from the ninth to the fifty-sixth day after the first onset of scarlet fever, mostly between the twentieth and thirtieth days. In nineteen cases peeling took place twice. No deaths resulted, but the second cases were on the average more grave than the first and were followed by complications in 60 per cent as against from 18 to 20 per cent in the first cases, milder complications being included. In Gottlieb's opinion the most probable explanation of the recurrence is cross infection from other patients with streptococci of different type than that which caused the original attack of scarlet fever. This assumption seems to him supported by the finding of different types of streptococci in different scarlet fever patients (Smith, Griffith) and by the occasional establishment in children in hospital wards of streptococci of different type than that originally established, to which the disorder was presumably due.

**Pulmonary Tuberculosis from Bovine Type of Bacillus.**—Determinations of type of these thirty-three cases were made by the State Serum Institute. Mourier thinks that transmission from cattle to man may have occurred in twenty-nine of the cases. The clinical course and prognosis, he says, apparently resemble those in pulmonary tuberculosis due to tubercle bacilli of the human type.

**Cevitamic Acid in "Schönlein-Henoch's Purpura."**—Daily intramuscular injections of cevitamic acid, in all 3,800 mg., administered to Lønberg's patient, a boy aged 4, had no effect on the course of the disease. There was no cevitamic acid deficiency before the start of treatment.

**Remission During Course of Leukemia.**—In Heinild and Schjeldt's case of acute myeloblastic leukemia, the number of white blood corpuscles became normal after treatment with cevitamic acid; at the end of the treatment the number of white blood corpuscles increased. In their case of chronic lymphatic leukemia, cessation of the tendency to hemorrhage and rise in the thrombocyte count occurred during the first treatment with cevitamic acid, which was accompanied by roentgen treatment; the hemorrhages also ceased on the second course of treatment with cevitamic acid. In their two cases of chronic myeloid leukemia, no direct effect of the treatment with cevitamic acid was seen, but the remission after the succeeding roentgen treatment was more complete than is usual in such cases.

**Infected Tonsils and Rheumatism in Children.**—Aitken declares that there is much evidence in support of the theory that an acute infection of the nasopharynx by hemolytic streptococcus has a definite relationship to attacks of acute rheumatism, and some evidence to support the opinion that chronically infected tonsils have an injurious effect on the rheumatic child in the sense that, although their removal may not prevent the onset of the disease, it does minimize the chance of serious cardiac complications and recurrences. A preliminary tonsillectomy, or one performed early during the course of the infection, may possibly, in the case of arthritis, render the heart less liable to be attacked, but not so in the case of chorea. Tonsillectomy in the case of carditis following arthritis seems to have a beneficial effect on the progress of the disease, but not in carditis following chorea. The analysis of 117 cases seems to show that the progress in those cases which did not require tonsillectomy and those in which tonsillectomy was done before the onset of juvenile rheumatism was rather more satisfactory than in those in which tonsillectomy was required at the onset of juvenile rheumatism. The patients who had not been tonsillectomized but who did not require tonsillectomy had the most satisfactory result, but those who had had complete tonsillectomy before the onset of the disease had nearly as good results.

**Rôle of Calcium in Tetany.**—Barnes and Greaves state that spontaneous overbreathing tetany occurs chiefly in neurotic and highly strung women. It is a manifestation most frequently of hysterical overbreathing, but in these patients it may show itself also after slight exertion, owing to overactivity of the respiratory center. Overbreathing tetany can be relieved either by the injection of calcium salts or by the production of an acidosis. It would seem, therefore, that two factors are involved in the production of the syndrome: the level of the calcium and the  $p_H$  of the blood. The object of the authors' investigations was to show that in their cases there was a definite alkalosis during tetany, and then to determine whether the onset of tetany was or was not associated with a fall in the calcium content of the cerebrospinal fluid, and hence of the diffusible calcium of the blood. The calcium in the plasma, serum and cerebrospinal fluid was estimated by a modification of the method of Kramer and Tisdall, as advised

by Beaumont and Dodds. Experimentally it was found that about thirty minutes of overbreathing is required before symptoms of this tetany start. This time was greatly reduced in all clinical cases. In the two clinical cases in which the alkali reserve was estimated it rose during tetany, as opposed to a fall in the experimental cases. This may be accounted for by the fact that either the time factor is insufficient to allow complete compensation by the transposition of alkalis to the tissues or it is a fundamental lack of ability on the part of these patients to perform this reaction which predisposes to overbreathing tetany. That alkalosis was present during tetany in the patients was shown by the rise of alkali reserve and by the increased  $p_H$  of the urine. It becomes a matter for speculation as to why some patients with alkalosis develop tetany while others do not. The authors believe that the fact that they were able to relieve overbreathing tetany by the injection of a solution of a calcium salt with a  $p_H$  greater than that of the blood seems to them to be strong evidence that the tetany is not the result of alkalosis alone. They suggest, therefore, that the onset of tetany may be dependent on the total calcium present in the circulation and the reaction of the blood. The common factor is the level of the diffusible calcium, which is greatly affected by slight changes in the reaction of the blood. If this is so it can be explained why tetany should not necessarily occur when the calcium of the blood is low, provided it is the protein bound fraction of the calcium which is reduced or that there is an acidosis, as in the cases of chronic nephritis described by de Wesselow. The premonitory symptoms of overbreathing tetany may pass unrecognized if they do not develop further. Only when voluntary hyperpnea is shown to lead rapidly to the onset of tetany does the true significance of these symptoms become apparent.

**Disposal of Fructose by Liver.**—Twenty-four hours after the administration of  $10_{460}$  mol of each of the aliphatic monovalent, saturated alcohols (methyl, ethyl, n-propyl, i-propyl, n-butyl, i-butyl, n-amyl, i-amyl and n-hexyl) Iida injected intravenously 1 Gm. of fructose per kilogram of body weight into rabbits and found that the curve of fructosemia after the administration of these alcohols was usually higher than before, and the difference of the height of the two curves was enlarged in accordance with an increase of carbon atoms of the alcohol; that is, the ascent of fructosemia was marked and its descent was retarded. Only methyl alcohol was the exception. Judging from the curve of fructosemia following the intravenous injection of fructose as a liver function test, he concludes that, with the exception of methyl alcohol, the toxicity of aliphatic monovalent saturated alcohols for the liver is in general gradually strengthened with an increase of the number of carbon atoms and molecular weight of the alcohol; in other words, that Richardson's law is applicable to the disposal of fructose by the liver as well as to the azorubin-S-excreting function of the liver. It is possible that the blood sugar may be influenced to some extent immediately after the administration of alcohol, and, accordingly, fructose closely connected with dextrose may also be changed more or less at this moment. However, twenty-four hours after the administration of alcohol any direct effect of alcohol on fructose is probably negligible, though alcohol may primarily injure the liver and secondarily influence the curve of fructosemia.

ently susceptible to breast carcinoma, the occurrence of which is held in abeyance by the absence of breast function.

It will be shown later that with proper dosage and sufficient length of treatment the genital and pituitary responses to estrogens can be duplicated under certain

conditions in the human being. It is, however, obvious that the choice of the clinical dose ultimately depends on many factors totally unrelated to animal experimentation. The dosage of estrogens cannot be computed purely on the basis of comparative weights, not only because there is a definite species variability in the response of organs to the principle but also because existing pathologic conditions in human organs often change the tissue response to a given dose of the substance.

METHOD OF STUDY OF RATE OF ABSORPTION AND EXCRETION OF ESTROGEN

For the purpose of studying these problems from the clinical standpoint, we selected forty-two hospital patients convalescing from various pelvic operations which included removal of both ovaries. That the blood

and urine of castrated women, maintained on an average hospital diet, contain only insignificant amounts of estrogen was verified in each instance. It was therefore assumed that the minimum quantity of estrogen capable of producing and maintaining in the blood and urine of the castrate a concentration of the substance comparable to that current during the premenstrual phase of regularly menstruating women would be an ideal substitution dose in patients with deficiencies of estro-

gen. This quantity may conveniently be called the "human castrate unit," which naturally varies with the product employed and the mode of administration. This quantity of the substance, being relatively within the limits of natural production, should not inhibit the gonadotropic function of the anterior pituitary lobe and therefore would not nullify the effects of other agents simultaneously employed in the hope of reestablishing a normal pituitary-ovarian balance. With the establishment of the maintenance dose of estrogen, larger doses may be employed when inhibition of the several functions of the anterior pituitary lobe is clinically indicated.

As a basis for comparative study, we utilized arbitrarily the accepted normal premenstrual ratio of 1 mouse unit of the active hormone in 40 cc. of blood<sup>13</sup> and 15 rat units in the twenty-four hour output of urine.<sup>14</sup> In more than 100 parallel analyses of blood and urine of women under treatment with varying doses of estrogen, we found this quantitative relationship undisturbed regardless of the amount of estrogen administered.

Since the urine content of active estrogens reflects fairly accurately the amount present in the circulating blood and since daily blood-estrogen tests are obviously impossible, this study on the rate of absorption and excretion of the product is based mainly on daily

\* Frank and Goldberger test performed on same date with positive result.

extraction of the entire output of urine. Blood studies were made intermittently in every instance and proved, with an occasional exception, corroborative of the urinary changes.

In this study on the rate of absorption and excretion of estrogen, oily solutions of estradiol benzoate (progyonon-B), estradiol (progyonon-DH), theelin (estrone) and theelol (estriol) were administered to the castrated women either hypodermically or orally in doses of from 300 to 50,000 rat units over periods varying from one to ten days.<sup>15</sup> The products were tested in our laboratory by the Allen-Doisy method.

OBSERVATIONS ON THE ADMINISTRATION OF A SINGLE HYPODERMIC DOSE OF ESTROGEN

In order to determine the proper interval for the hypodermic use of estrogen, a single dose of from 1,000 to 10,000 rat units was given to twelve surgically castrated women and the entire output of urine was extracted daily for a period of five days. Discounting

**Porphyria in Diagnosis of Extra-Uterine Pregnancy.**—Neuweiler shows that the diagnosis of extra-uterine pregnancy may cause difficulties, as in the case of perforated extra-uterine pregnancy with the formation of hematocele. In this condition the symptoms are not alarming, the pains are not severe and the mild internal hemorrhages are not readily demonstrable; in short, the entire symptomatology is not characteristic, so that even the experienced examiner finds it difficult to differentiate it from adnexitis. The author directs attention to a chemical test, which demonstrates the presence of ether-soluble porphyrin (coproporphyrin) in the urine and which he found positive in cases of hematocele. He admits that an excessive coproporphyrinuria occurs frequently in prolonged febrile conditions, but in hematocele it appears after a relatively short time. In adnexitides, however, if they are not accompanied by severe, prolonged fever, the porphyrin reaction in the urine is normal. Since it is the differentiation between adnexitis and hematocele that is especially difficult, the appearance of coproporphyrin in the urine together with the general symptoms of the disorder is an important, perhaps the decisive, sign in the diagnosis of extra-uterine pregnancy. Since it may be accepted that porphyrin develops as the result of the decomposition of blood, its increased elimination may be expected also in other hemorrhagic abdominal tumors, such as ovarian tumors with torsion of the pedicle or myomas with extensive hemorrhagic infarction. This is actually the fact and it is therefore impossible to base the differentiation between hemorrhagically infarcted tumors and extra-uterine pregnancy on the outcome of the porphyrin test. However, the diagnosis of these tumors is usually possible without much difficulty.

**Depression in the Puerperium.**—Nürnberg describes the clinical histories of three women who in the first few days of the puerperium developed a more or less pronounced depressive mood with anxiety, hypochondria and feelings of inferiority. The author thinks that, in view of its appearance shortly after delivery, the condition may be grouped with the depressive puerperal psychoses. To be sure, the symptoms in the reported cases were not as pronounced as in those recorded in the psychiatric literature. No definite cause could be found for the depressive states, but in the three women the psychic disturbances disappeared following the subcutaneous injection of extract of the anterior lobe of the hypophysis. The author admits that the prognosis of these conditions might be favorable even without treatment, but he considers it helpful to know that they can be promptly counteracted by extract of the anterior lobe of the hypophysis.

**Manual Dilation of Os Uteri.**—Reist shows that, if a careful technic is employed and asepsis is preserved, manual dilation of the os uteri produces in suitable cases the desired results; that is, a rapid termination of the period of dilatation. It is helpful in certain cases in which the dilatation is retarded or has completely stopped, because it permits a spontaneous delivery in a manner that involves no danger for either mother or child. Manual dilation of the os uteri can be used also for the rapid opening of the soft parts for the purpose of an immediate delivery in cases in which danger appears suddenly for either mother or child. The author uses it in from 4 to 6 per cent of all deliveries and says that, if the method is used according to the indications outlined by him, there is no danger that it will become an uncritically employed obstetric intervention. On the contrary, its use will reduce the more extensive vaginal obstetric interventions and the infant mortality during birth.

\*Short Waves in Inflammation. E. V. Salerno.—p. 2563.

**Anesthesia of Ganglions.**—Albanese says that anesthesia of the stellate ganglion has to be associated with that of the second and third thoracic ganglions to establish the criteria for indica-

tions of resection of the ganglions. Leriche's technic has several disadvantages and only the stellate ganglion is anesthetized. In the author's technic the needle follows a short and direct course through an area which has no important nerves and vessels, the points of reference (neck of the first and second ribs) are easy to find and the stellate as well as the upper thoracic ganglions can be anesthetized. The technic is as follows: The patient is placed in the dorsal decubitus with a small pillow under the shoulders and the head in extension and rotation toward the opposite side to that in which the needle is to be introduced. A line is drawn from the tip of the angle of the lower jaw to the central point on the clavicle. The needle, which is 8 cm. long, is introduced on the line, or a few millimeters in front of it, and two fingerbreadths above the clavicle. If the external jugular vein is found at that point, the needle is introduced a few millimeters in front of it. The needle is directed inward, downward and backward, passes the anterior scalenus muscle and touches the neck of the first rib. The stellate ganglion is slightly forward. A dose of 5 or 10 cc. of a 2 per cent solution of procaine hydrochloride (without epinephrine) is injected. The needle is then slightly withdrawn, directed in front of the neck of the first rib and gently pushed in to touch the neck of the second rib. The second thoracic ganglion is injected at this point. By repeating the maneuver with the needle directed in front of the neck of the second rib to touch the third rib, the third thoracic ganglion can be injected at this point. The author does not specify the dose of 2 per cent solution of procaine hydrochloride that is injected in the second and third thoracic ganglions.

### Short Wave Irradiation in Treatment of Inflammation.

—Salerno reports satisfactory results from short wave irradiations in the treatment of several processes of chronic, subacute and acute inflammation as well as in certain diseases with angiospasm or viscerospasm of the smooth muscles. The number of irradiations varied from seven to ten given daily or every other day for a duration of from ten to forty minutes. Short waves constitute the best physical therapeutic agent against inflammation.

**Vitamin C in the Placenta.**—Neuweiler was able to demonstrate vitamin C in the placenta by titration with indophenol, with methylene blue, according to the ferment method and by animal experiment. He found that the concentration of vitamin C in the extract is largely dependent on the method of extraction and that the technic of Fujita does not give reliable values. During the early part of pregnancy the vitamin C content seems to be slightly higher, but the author admits that this contradicts former observations and cannot be definitely proved. It appears that in the maternal side of the placenta the vitamin C content is higher than in the portion that is under the chorion plate. The vitamin C content of the placenta is dependent on the vitamin C supply available to the maternal organism. Histologic studies seem to indicate that vitamin C is stored chiefly in the outer layer of the chorionic villi. Thus the placenta seems to be a storage organ for vitamin C, probably to insure a vitamin supply for the fetus.

**Trichomonas Vaginalis in Pregnant Women.**—In studies on pregnant women, Szendi investigated the incidence of infestation with Trichomonas vaginalis. The infestation with Trichomonas vaginalis was discovered in 44 per cent of the 200 cases examined. In about one third of the cases the infestation caused no symptoms, in others there was foamy discharge and in about 30 per cent there was inflammation (vulvovaginitis). The discharge is caused by an acute suppurating inflammation of the vaginal wall with intradermal and subepidermal vesicles

inally intended for hypodermic use, is more readily absorbed from the gastro-intestinal tract than either estriol or estradiol.

Most significant is the comparison of observations on the ratio between the hypodermic and the oral doses of estrogenic substance in the human being. Analysis of the figures in tables 3 and 4 shows that the hypodermic administration of estrogen in the human being is only twice as effective as the oral route when judged by the rate of absorption and excretion. It varies considerably with the product employed—theelin being most readily absorbed from the gastro-intestinal tract and yielding a ratio of even less than 1 to 2. These observations clearly illustrate the fallacy of broadly interpreting animal experimentation in terms of human applicability. In the rhesus monkey, for instance, the ratio between the hypodermic and the oral doses of estrogen is deemed to be 1 to 5.<sup>16</sup> It will be shown later, however, that even in the human being the ratio of 1 to 2 is not applicable in the treatment of gonorrheal vulvovaginitis of children, in whom an oral dose five times the hypodermic is required to produce a comparable clinical effect on the vaginal mucosa.

#### THE CLINICAL USES OF ESTROGEN

Therapeutically, estrogen may be administered in various conditions with the following objectives in mind:

1. To overcome uterine hypoplasia resulting from a natural deficiency of estrogen, as seen in most instances of amenorrhea, hypomenorrhea and dysmenorrhea and occasionally in the dysfunctional sterility of regularly menstruating women. In order to avoid the undesirable, though temporary and totally harmless, pituitary inhibition from excessive and prolonged administration of the product, the daily dose should theoretically be computed on the basis of complementing actual or relative deficiency of production, as indicated by the size of the uterus and the hormone content of the blood and urine of the patient.

2. To inhibit one or more of the several functions of the anterior pituitary lobe by inducing a constant hyperestrinemia in the treatment of such conditions as the severe menopausal syndrome,<sup>17</sup> the lobular form of abnormal breast hyperplasia,<sup>18</sup> premenstrual migraine,<sup>19</sup> pituitary hyperthyroidism<sup>20</sup> and selected cases of diabetes mellitus.<sup>21</sup> The utility of employing in these conditions a dose of estrogen totally incapable of inhibiting the respective hyperfunctional states of the anterior hypophysis is shown by the experience of Pratt<sup>22</sup> in climacteric patients and of Collens<sup>23</sup> in the treatment of diabetes mellitus. Both employed quantities of the substance which, according to the foregoing studies on optimal dosage, could only slightly

increase the estrogen content of the blood even in women with adequate ovarian activity.

3. To produce a purely local growth effect in the vaginal mucosa of children suffering from vulvovaginitis<sup>24</sup> and of postmenopausal women suffering from senile vaginitis.<sup>25</sup> It seems that for this purpose the local application of the substance in the form of vaginal pessaries is most effective.<sup>26</sup>

4. To evoke a pituitary-ovarian response in cases of severe amenorrhea by employing intermittently massive doses, such as 300,000 rat units over a period of one week.<sup>9</sup>

#### EFFECT ON AMENORRHEA

Estrogens produce no stimulative effect on the ovaries. They are usually employed in conjunction with other measures, such as low-dosage irradiation of the hypophysis and gonads,<sup>27</sup> to overcome the associated hypoplasia of the uterus. When employed alone, they are most effective when the uterine atrophy is merely the residuum of a previously existing ovarian deficiency—the so-called hyperhormonal amenorrhea of Zondek.<sup>28</sup> The latter is a condition wherein there is a normal supply of the estrogen, not sufficient, however, to overcome the uterine atrophy acquired during a previously existing ovarian deficiency of long duration. Theoretically, the maintenance dose of 500 rat units daily when given orally or 1,000 rat units every fourth day when administered hypodermically (vide supra) should be effective substitution therapy. But, owing to the pathologic state of the uterus, far larger doses are required to produce an impression. It was shown by Kaufmann<sup>29</sup> and Clauberg<sup>30</sup> and amply verified by our experience that the minimum quantity of estrogen capable of evoking an adequate proliferative phase in the atrophic endometrium of the castrated woman is 50,000 rat units per month. Smaller quantities, administered over a long period of time, may produce an effect in the form of uterine bleeding, but the endometrial growth is far below the natural state.<sup>31</sup>

Of twenty-eight amenorrheic patients treated with large doses of estrogen alone, five had never menstruated (primary amenorrhea), nine had no menstrual periods during the year preceding treatment and fourteen had menstrual intervals of four or more months but less than twelve months. The five patients with primary amenorrhea presented a hopeless degree of uterine atrophy. They were given 10,000 rat units of estradiol benzoate hypodermically at intervals of four days for periods varying from two to eight months. Two of the five patients menstruated almost cyclically during treatment; the remaining three failed to respond even temporarily. The patient who received the largest quantity of the substance—a total of 675,000 rat units—showed, on repeated uterine curettages, no endo-

that roentgenoscopy is the most reliable diagnostic method. He points out that some authors are of the opinion that a congenital defect of the diaphragmatic musculature is the most important factor in the pathogenesis of diaphragmatic relaxation. This theory is based on necrotic observations during early childhood, on the frequent occurrence of diaphragmatic relaxation with other congenital defects, such as harelip, cleft palate and spina bifida, and on the almost exclusive sinistral development of the relaxation. The author points out further that another group of investigators considers diaphragmatic relaxation the result of lesions of the phrenic nerve. It has been stated that processes which cause changes in the phrenic nerve should be searched for chiefly in the region of the fourth cervical vertebra. They may be tumors, spondylitis, fractures, luxations, pachymeningitis, spinal hemorrhages and tuberculous and syphilitic meningeal processes. In the present patient the diaphragmatic relaxation was the result of a paralysis of the phrenic nerve, which in turn was produced by a tumor of the fourth cervical vertebra.

\*Local Anesthesia in Some Minor Gynecologic Operations. F. Raucherberger.—p. 936.

**Local Anesthesia in Minor Gynecologic Operations.**—Raucherberger calls attention to the fact that local anesthesia in gynecologic cases has lately attained wide application, especially in cases of miscarriage or abortion and in cases in which the neck of the uterus has to be dilated, which usually is an extremely painful ordeal necessitating a general anesthetic and more adequate assistance and which often results in a disturbance of the lungs. All this has been done away with by application of local anesthesia. During the last two years the author has performed operations of various types in 340 cases with satisfactory results: some were plastic operations and there was even a cesarean section. Although he has tried other preparations for local anesthesia, he found none as satisfactory as that made up of 0.2 Gm. of procaine hydrochloride, 2 drops of epinephrine solution, 0.03 Gm. of potassium sulfate, 0.06 Gm. of sodium chloride and 20 cc. of distilled water.

### Sovetskaya Khirurgi, Moscow

Pp. 377-552 (No. 3) 1936. Partial Index

- Surgery of Cardiac Diseases. P. A. Gertsen.—p. 379.

Four Hundred Punctures of Posterior Cystern of Brain. I. S. Royzen.—p. 427.  
Postanginal Peritonitis. V. V. Popov.—p. 434.

**Transfusion of Conserved Blood.**—According to Belenkiy, conserved blood undergoes *in vitro* biochemical and morphologic alterations of a destructive character terminating in a complete loss of its functional characteristics. These alterations depend to some extent on the character of the medium in which it is conserved. Blood undergoes less deterioration in a dextrose-citrate solution than in a citrate-saline solution. Because of the progressive character of the deterioration, the author feels that conserved blood should be regarded as a medium containing morphologic and chemical components of the blood rather than blood tissue. The properties of the conserved blood permit its use for the purpose of blood replacement as well as for that of stimulation. Excellent therapeutic effect was obtained in chronic anemia of various types in which the usual medicinal and dietetic regimens failed. It likewise proved its efficiency in diseases associated with disturbed metabolism and trophic dysfunction of the nervous system. A comparative study of the effect of fresh blood transfusions in the same type of disease demonstrated the inferiority of the conserved blood, especially when kept for twelve or more days. The effect of transfusion of conserved blood in acute hemorrhage with or without shock was prompt and efficient. The gravely lowered blood pressure rapidly rose to normal levels and remained so. This effect was always more pronounced

when a relatively freshly conserved blood, such as that of from three to seven days, was used. Cases of acute anemia or of traumatic shock are less likely to have a reaction following the transfusion of conserved blood than following that of fresh blood. The hemostatic effect of conserved blood in hemorrhagic diathesis was found to be inferior to that of fresh blood. The author concludes that transfusion of fresh blood is still the method of choice but that under certain conditions, such as mass traumatism in a combat, the use of conserved blood may have certain advantages over the former.

### Folia Medicinæ Internæ Orientalia, Jerusalem

2: 87-176 (April) 1936. Partial Index

\*Disinfection Experiments on Fruits from Various Origins and Comparative Studies on Efficacy of Various Methods of Disinfection. L. Olitzki and J. Gurevitch.—p. 157.

**Neurologic Syndrome Occurring in Palestine.**—Zondek and Stark describe a neurologic disorder that they observed in a considerable number of persons during the hot summer months in Palestine. An attempt failed to identify the disorder as one already known. It is characterized by violent headache, pains in the limbs, increased psychic irritability, spastic disturbances in the reflexes and occasional subfebrile temperature. There are no other disturbances on the part of the central nervous system. The disorder is transient. It is assumed that the disorder is caused by an increase in cerebral pressure resulting from abnormal insolation. The authors give the clinical histories of six cases.

**Disinfection Experiments on Fruits.**—Olitzki and Gurevitch demonstrate that the disinfection of fruits before consumption is an indispensable hygienic measure in Palestine. In order to prevent bacillary infections, the authors recommend that the fruits be dipped three times into a 1:10,000 solution of potassium permanganate with 0.5 per cent of acetic acid. After each dipping the fruits should be rinsed, but the potassium permanganate should act each time for five minutes. However, the authors admit that chemical disinfectants as a rule have only a slight effect on protozoa and worm eggs. Like other investigators, they found that boiling water is the only effective agent against amebas. They reach the conclusion that, whenever there is an increase in cases of typhoid and bacillary dysentery, fruits should be disinfected with dilute potassium permanganate. On the other hand, disinfection with boiling water is imperative in all cases in which there is a possibility of infection with intestinal protozoa.

### Hospitalstidende, Copenhagen

79: 1137-1148 (Oct. 27) 1936

- \*Investigations on Sedimentation Reaction in Dementia Paralytica. K. H. Fremming and J. Madsen.—p. 1137.

**Sedimentation Reaction in Dementia Paralytica.**—Fremming and Madsen state that certain normal sedimentation reaction was found in only 20 per cent of fifty-three cases of recent cerebrospinal syphilis, mainly dementia paralytica; the sedimentation reaction was definitely increased in about 50 per cent. Intercurrent somatic disorders were established in only three cases as being the cause of the high reaction. Low sedimentation reaction and marked changes in the spinal fluid point to a more superficial form of cerebral syphilis and constitute a favorable prognostic sign, while low sedimentation reaction and slight changes in the spinal fluid indicate an older stationary process with but slight prospect of remission after malaria treatment. High sedimentation reaction in a patient with weak changes in the spinal fluid points to a complicating medical disorder. High sedimentation reaction, if not due to intercurrent diseases, does not contraindicate malaria treatment. Under malaria treatment a marked rise in the sedimentation reaction occurs, but in differing degrees. In some cases the sedimentation reaction falls after the fourth or fifth attack of fever, in spite of continued rises in temperature; further investigations are necessary to determine whether this depends on hepatic injury with consequent lowered fibrin production.

EFFECT ON THE ALVEOLAR TYPE OF ABNORMAL  
BREAST HYPERPLASIA

Leriche<sup>35</sup> and Whitehouse<sup>36</sup> obtained considerable success with the use of estrogen in the treatment of painful, nodular breasts (mazoplasia or adenosis). The nipple bleeding, which is present in 7 per cent of breast adenosis,<sup>37</sup> was found by one of us<sup>18</sup> to be equally responsive to the administration of the substance. Four of five patients thus treated have remained free from symptoms since 1933. The fifth patient, who apparently had a duct papilloma, as shown by the appearance of blood when pressure was applied in the vicinity of the nipple, was unaffected by the treatment. Nevertheless, she still shows no evidence of a malignant condition of the breast.

Nipple bleeding, moreover, often occurs without palpable breast nodularity. Its benignancy is thus characterized by Bloodgood:<sup>38</sup> "I have no evidence that a woman who has a discharge from one or both nipples, and whose breasts on palpation are found free from tumors, runs any more risk of cancer than a woman who has pain and no palpable tumor or any female who has neither." There is no doubt that conservative surgery is indicated in cases of nipple bleeding associated with a palpable mass or a well circumscribed opacity under transillumination but, in the absence of a palpable nodule or in the presence of numerous, widely scattered nodules, recourse to operative measures entails useless sacrifice of the breast, since nipple bleeding, as shown by Deaver,<sup>39</sup> is the first symptom in only 1 per cent of cases of mammary carcinoma.

Thus far, we have followed up for a period averaging sixteen months three more women similarly treated for nipple bleeding and multiple nodules of the breast. One of them was relieved in the course of a month with the use of 29,000 rat units of the substance. The second patient had bilateral nipple bleeding and galactorrhea for ten months prior to treatment. She was given a total of 324,000 rat units of estradiol benzoate hypodermically in the course of seven months and remained free from both the galactorrhea and the nipple bleeding during a follow-up period of nine months. The third patient had profuse unilateral nipple bleeding with multiple nodules in the axillary portion of the left breast. She received a total of 590,000 rat units of estradiol benzoate hypodermically over a period of six months without improvement of the nodularity or the associated nipple bleeding. She refuses removal of the lesion, which has existed nearly two years.

## EFFECT ON VULVOVAGINITIS

The treatment of gonorrheal vaginitis of children by means of estrogen, first suggested by Lewis,<sup>24</sup> provoked considerable discussion in the medical literature, some favorable and others entirely unfavorable. Thus, for instance, Witherspoon<sup>40</sup> found this form of treatment entirely ineffective. From the discordant reports, it is

evident that difference in dosage, length of treatment, mode of administration and the failure to recognize extragenital foci of infection, not within the influence of the substance, account for the discordant results reported.

Experimentally, Berger<sup>41</sup> has shown that one tenth of the necessary hypodermic dose of estrogen is capable of evoking estrus in the castrated adult rat when instilled directly into the vaginal canal. Clinically, TeLinde<sup>26</sup> observed that estrogen (amniotin) administered in the form of vaginal suppositories is superior to any other method of treating vulvovaginitis. Thus far, our experience with this form of treatment has been too limited to warrant a conclusion as to its effectiveness. A detailed report concerning the relative merits of the various methods of treating vulvovaginitis will be prepared shortly under the supervision of the Philadelphia Institute for Medical Research.

Thus far, we have followed up for a period of from four to thirty-two months ninety-three children with gonococcic vulvovaginitis observed in private practice, in the clinic and in hospital wards. Sixty of the children received hypodermic injections of from 1,000 to 1,500 rat units of estradiol benzoate every other day for a period of eight weeks, though four or five consecutive negative vaginal smears were usually obtained after the third or fourth week of treatment. Only five of the sixty (8 per cent) showed a recurrence of the infection during a follow-up period of four or more months. Nine children received hypodermic injections of from 1,000 to 1,500 rat units of the same substance every other day for a period of only four or five weeks. Four of the nine had recurrences during the first four months of the follow-up period. Eighteen children received 500 rat units of the substance every other day during a period of from five to eight weeks. Six (33⅓ per cent) had a recurrence of the infection during a follow-up period of four or more months. Six children were given 1,500 rat units of estradiol (progyon-DH) orally, twice daily, for a period of eight weeks. Three of the six had a recurrence of the infection during a follow-up period of four or more months. None of the children received any local treatment other than cleansing of the external genitalia.

From the foregoing data, it seems that the optimal dose and length of treatment of gonorrheal vulvovaginitis is 1,000 or more rat units given hypodermically every other day for a period of not less than eight weeks.

The safety of administering such large doses of estrogen to children of tender age is yet to be determined. Only one of the treated children has thus far reached the age of puberty. The menarche appeared at the usual time. She has been menstruating regularly for a period of a year. Five of the ninety-three children had some uterine bleeding for one or two days during the period of treatment; nineteen showed definite enlargement of the breast while under treatment and for a period of a month thereafter; nine, the youngest of whom was 2 years old, showed evidence of growth of pubic hair, which disappeared after withdrawal of treatment. No constitutional effects were observed in any of the children.

## STUDIES ON THE OPTIMAL DOSAGE OF ESTROGENS

AN EXPERIMENTAL AND CLINICAL EVALUATION

CHARLES MAZER, M.D.  
AND  
S. LEON ISRAEL, M.D.  
PHILADELPHIA

With the recent availability of chemically pure and highly concentrated estrogenic products, the medical profession is confronted with the problems of the margin of safety, therapeutic indications and optimal dosage. In a previous study on the constitutional effects of relatively large doses of estrogens, we<sup>1</sup> found that the administration of from 100,000 to 260,000 rat units of the principle, given in divided doses over a period of from two to three months, produces no appreciable changes in body weight, basal metabolism, blood pressure, blood count, coagulation and bleeding times, blood chemistry and urine. The present study was undertaken in an attempt to evaluate the indications for the clinical use of estrogens, their respective optimal dosage and the most effective modes of administration.

### THE PHYSIOLOGIC EFFECTS OF ESTROGEN IN THE EXPERIMENTAL ANIMAL

Clinical studies in optimal dosage of a new therapeutic agent are by necessity based primarily on the varied responses of animal organs to different quantities of the product. An analysis of the authentic current literature on the effects of estrogens in laboratory animals permits the following deductions:

1. The uterine growth response to the principle is directly proportional to the quantity administered and the length of treatment but varies considerably with the product employed and the mode of administration. Thus, for instance, on the basis of the rat unit, estriol is least effective<sup>2</sup> and estradiol benzoate most potent in producing uterine growth and vascularity.<sup>3</sup>

2. The substance has no direct effect on the gonads even when administered for a relatively long time and

in quantities far greater than the ovaries normally produce. Indirectly, it does produce ovarian damage through inhibition of the gonad-stimulating function of the anterior pituitary lobe.<sup>4</sup> The ovarian damage is, however, temporary<sup>5</sup> and without effect on future fertility.<sup>6</sup> Relatively large doses also inhibit the diabetogenic function of the hypophysis.<sup>7</sup> The principal factors productive of pituitary inhibition are the size of the dose and the length of treatment. Twenty rat units (100 mouse units) injected in infantile rats twice weekly over a period of four months produces no ill effects. When, however, the dose is increased to 200 or more rat units (1,000 mouse units), both the gonadotropic and the growth-producing functions of the anterior pituitary lobe are markedly inhibited, as evidenced by the development of gonadal atrophy and dwarfism.<sup>8</sup> Single or multiple doses of 500 or more rat units given over a period of only one week produce an opposite pituitary-ovarian effect in the infantile rat and rabbit; namely, increased gonad-stimulating function and secondary ovarian growth.<sup>9</sup>

3. Administration of estrogen, in adequate quantities, prevents and corrects the morphologic and hyperfunctional castration changes of the hypophysis.<sup>10</sup>

4. The substance produces extensive growth of the duct system of the mammary glands of male and female animals and prepares the acini and terminal ducts for the action of the pituitary lactogenic principle.<sup>11</sup> In male mice of a strain in which only the females ordinarily develop spontaneous mammary adenocarcinomas, long continued administration of estrogen leads to the development of malignant tumors.<sup>12</sup> It is, however, evident that the males of this strain of mice are inher-

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

Read before the Section on Pharmacology and Therapeutics at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

The international unit (weight unit) of estrogen is one-tenth microgram. The ratio between the rat unit and the international unit varies with the chemical composition of the product and its purity. In our laboratory various samples of estrone yielded from 500,000 to 1,000,000 rat units per gram; estriol, 150,000 rat units per gram; estradiol, 6,500,000 rat units per gram, and estradiol benzoate 5,500,000 rat units per gram. It is therefore evident that the use of the rat unit is preferable when dealing with the several estrogens.

Lancereaux, who in 1866 differentiated between interstitial and gummatous syphilis and described white and yellow areas of connective tissue throughout the heart. Ehrlich in 1880 described a myocardium containing small gray-white foci, which he thought were caused by syphilis and had resulted from syphilitic obliteration of the arteries. During 1894 Hektoen,<sup>3</sup> who was at Chiari's clinic, reported syphilis involving the muscle of a child's heart characterized by round white areas as large as 1 cm. in diameter. His description of the cellular changes is quoted and is in accord with those later described by Warthin: "There were extensive infiltrations into and between the muscular bundles with rounded and oval nucleated cells, usually embedded in fairly circumscribed districts and seems to proceed in the main from the adventitia of the smaller vessels immediately around which the proliferation is most marked."

Coronary artery disease and syphilis were not associated by the earlier pathologists, although Lancereaux must have known that these arteries were affected, for he mentioned the occurrence of an obliterating endarteritis. Saphir noted in his review that Billings in 1911 found that syphilis caused endarteritis of the coronaries and that similar reports of coronary disorder were made by Brooks in 1921, Maher in 1930 and Moritz in 1931.

Since 1910, reports of myocardial syphilitic disease have been numerous and thorough. Scientific and convincing descriptions have been given by Warthin<sup>4</sup> (1911 and 1912), and to him is given the credit for the modern conception of a process characterized by the presence of irritative or inflammatory processes with lymphocytic and plasma cell infiltration in the stroma and about the blood vessels. Cabot<sup>5</sup> in 1914 observed thirty-two myocardial syphilitic cases in a group of 600. Allbutt<sup>6</sup> in 1915 made the statement that syphilis was frequently present simultaneously in the heart and the aorta. Lemann and Mattes<sup>7</sup> in 1920 examined fifty hearts presenting aortic lesions and found lymphocytic infiltrations in the hearts of twenty-four; and in 1923 Reid,<sup>8</sup> after finding seven syphilitic hearts in 100 necropsies, stated that every case of syphilis was potentially one of heart disease. Since 1925 only a few reports have been made: two by Paullin<sup>9</sup> in 1930 and another by myself<sup>10</sup> in 1933 in which I made an attempt to give adequate pathologic descriptions of the coronary lesions involved in myocardial syphilis. In May 1935 Magill<sup>11</sup> reported twenty patients under 46 years of age who had cardiac decompensation without any explanation as to the cause other than syphilis. The clinical features were enlargement of the heart without hypertension, arteriosclerosis and organic valvular damage. Sections from the hearts of all patients

in this group showed round cell infiltrations, and each patient had a positive blood Wassermann reaction.

Saphir's<sup>2</sup> monograph on the problem offers many aggressive arguments against myocardial syphilis. He thoroughly attacks the histologic criteria and feels that other conditions such as typhoid, streptococcal infections, pneumonia, diphtheria and arteriosclerosis may cause a cellular response similar to that caused by syphilis. He indicates very reasonably and scientifically his doubts as to the finding of spirochetes in heart tissue. He feels that spirochetes described as being "broken up" or "drawn out" or "fragmented in type" should be disregarded. Still further, he recalled a true fact: that no one could find spirochetes as easily as did Warthin and his assistants. Finally, he gives his personal experience in which he stained sections from 130 aortic syphilitic hearts, in which forty-one had involved coronary arteries. In none of the 130 hearts did he find typical spirochetes. He ended this interesting experiment by examining coverslips according to the Warthin-Starry technic and demonstrated artefacts that resembled spirochetes.

While willing to agree that I could not find the spirochetes with Warthin's facility, I feel that years of experience had taught Dr. Warthin more about heart forms of spirochetes than was known by any other living pathologist, and on this fact one is treading on thin ice when one presumably suspects that Warthin saw artefacts and called such artefacts spirochetes. A few practical facts about spirochetes that are remembered by histologists in general must also be considered. Spirochetes, in my opinion, do elongate, separate and fragment in syphilitic lesions, and at times they may obscure themselves by their twists, spirals and dissimilar appearances as compared to spirochetes in fetal or acute syphilitic ulcerations. One must admit further that as the syphilis grows older the spirochetes become hidden, quiescent and inactive. Treatment also tends to obscure them.

Thus, the controversy seethes in authoritative responsibility, and while I admire Saphir's splendid negative observations I feel that I must accept Warthin's contentions as correct; I feel supported by my own observations and by the similar acceptance of his work by other investigators. One cannot help but be greatly impressed by the statement in which Stokes<sup>12</sup> said: "Personally, and from a number of experiences in spirochete staining, and through Warthin's courtesy in allowing me to see a number of his preparations, I believe that we must yield to him as our master in the matter, and ascribe to technical difficulties many of the reported failures to confirm his findings."

#### INCIDENCE AND OCCURRENCE, TYPES AND METHODS OF MANIFESTATION AND ONSET

Syphilitic myocarditis in our community is more commonly found in the Negro male, yet as our records enlarge in number there seems an increasing total of females with the disease. In a former study of my records prior to 1932 I found syphilitic heart disease in 20 per cent of 110 necropsies and that the myocardium was probably involved in twenty of that group. Since 1932 we have had an active therapeutic clinic, and syphilitic heart diseases of all types appear to be on a decline. A recent review of 300 autopsies revealed seventeen grossly involved hearts and aortas in which twelve showed marked aortitis with six aneurysms. A

slight individual variations, a perusal of table 1 shows that the hypodermic administration of a single dose of 1,000 rat units of theelin or estradiol benzoate in oil maintains a normal level of estrogen in the blood, as reflected by the amount excreted in the urine, for a period of four days. Larger doses of from 5,000 to 10,000 rat units produce a temporary hyperestrinemia, which invariably reaches the normal premenstrual level on the fourth or fifth day.

On the basis of only two observations, it seems probable that theelin is as slowly absorbed from the skin as its chemically modified counterpart, estradiol benzoate. The latter is, however, far more soluble in oil and can be given in larger doses when necessary.

It is interesting to note the quantitative relationship between the amount of estrogen administered and that excreted (chart 1). The rate of excretion is so proportionate with the dose administered that all the demonstrable estrogen is eliminated by the fifth day,

\* Frank and Goldberger test performed on same date with positive result.

irrespective of the size of the dose. This is true also when an adequate quantity of the substance is administered orally as a single dose (table 2).

#### OBSERVATIONS ON THE ADMINISTRATION OF A DAILY HYPODERMIC DOSE OF ESTROGEN

Although the daily administration of estrogens hypodermically is not at all feasible in private practice, it seemed advisable to include a small series so treated in this study for the purpose of comparison. Analysis of table 3 shows that even 500 rat units administered hypodermically daily produces an abnormally high concentration of the principle in the blood, as reflected by the amount excreted by the kidneys daily.

#### OBSERVATIONS ON THE ADMINISTRATION OF DAILY ORAL DOSES OF ESTROGEN

Our largest series of observations are based on the most practical mode of administration of relatively small doses of estrogens—the oral route. Data relative to oral dosage to supplant the better known hypodermic variants are urgently needed. To that end, twenty-one surgically castrated women were given estrogens orally in doses of from 200 to 6,000 rat units daily in the

form of an oily solution on buttered bread. From the data recorded in tables 2 and 4, it is apparent that estrogens are readily absorbed from the human gastrointestinal tract. The degree of absorption, as reflected in the blood and urine levels of the principle, varies considerably with the product and the amount admin-

Chart 1.—Schematic representation of the quantitative relationship between the size of a single dose of estradiol benzoate and the amount excreted daily by the kidneys. Note that, regardless of the size of the dose, within the limits mentioned, the amount excreted on the fifth day is the same.

istered. That the commercially available products yield quite different rates of absorption, as reflected by the amount excreted in the urine, is visualized in the composite graph (chart 2). It demonstrates the average excretion values for each of the three products employed at an average daily dosage of 1,000 rat units. It is herein emphasized that no inference concerning the relative therapeutic effectiveness of the three substances administered orally may be drawn from this

Chart 2.—Schematic representation of the differences in the rates of excretion of the three estrogenic substances—theelin (solid line), estradiol (broken line) and estriol (dots and dashes)—when administered orally in daily doses of 1,000 rat units.

study. A careful analysis of table 4 shows that the minimum daily oral dose of either theelin or estradiol capable of maintaining a premenstrual level in the blood of the castrated woman is approximately 500 rat units and that the claim of greater absorbability of estriol when administered orally is not supported by this study. On the contrary, it seems that theelin, orig-

base is seen. The coronaries are most often involved at their openings, which are narrowed, presumably by the effects of the aortic distortion; but the coronaries may be, and often are, involved by narrowing of the lumens, puckering, corrugations, swellings and small sacculations, with interspersing yellow depositions extending for a distance of 5 or more centimeters. At

Fig. 3 (case 2).—Gross appearance of heart, showing syphilitic cavity with two openings in muscle at point near aortic base. The aorta appears quite normal except for small lesion near one cusp.

different times I have observed one of the coronaries extensively damaged and the other artery apparently normal.

In one or more instances I have found small aneurysms to be present a short distance from the aortic ostium. Not infrequently the coronaries have the effects of arteriosclerosis and syphilis combined, and only microscopic study will permit differentiation of the lesions. Usually in such lesions the arteries are diffusely damaged from ostia to deep terminals and are inclined to brittleness and have an unusual amount of spotty yellow color. Undoubtedly, as a differentiation point, sclerosis seems to begin in the terminals and goes to the openings of the large vessels. Syphilis is a reverse process and begins first in the mouths of the vessels and spreads downward to the small arterial ends.

In a previous report I<sup>10</sup> classified all the coronary groups that I have observed and to date have no reason to add to or change those observations.

Occasionally I have found occluded coronary twigs with subsequent inflammation in the muscle, and microscopic study would show early infiltrations of leukocytes with a good number of lymphocytes. Often I have found that in occlusion of the coronaries the processes of syphilis and atheroma are associated.

Histologically, I am in total agreement that the typical and constant tissue reaction is one in which lymphocytes, plasma cells and fibroblasts are usually around the vessels and in the connective tissue stroma, with the added fact that in the coronaries most often the picture is one of intimal thickening by endothelial proliferation, hyalinization and scarring by fibroblasts in the media, with considerable collection of islands of lymphocytes in the adventitia.

#### CLINICAL OBSERVATIONS

Seven of the patients were males and three were females. The eldest was a man of 56 and the youngest a man of 26; the group had an average age incidence of 37 years.

The blood pressures ranged from 160 systolic and 100 diastolic with an average blood pressure of 130 systolic and 73 diastolic. Four of these patients had a mild aortic deficiency, but the diastolic pressure never dropped below 40 mm. of mercury.

It has been difficult to get from patients an accurate story that would give a definite idea of the earliest symptoms of myocardial syphilis. I have, however, studied a number of them sufficiently to believe that the earliest symptoms are slight cardiac pain, which is variable in duration and severity, associated with extra beats (and skipping heart). Those symptoms, however, are usually not severe enough to incapacitate the patient completely but do cause a diminishing muscular power, and the patient has observed his inability to work or exercise with his former facility and realizes that extra activity on his part, such as excessive walking, lifting or climbing stairs, would exaggerate his pain and produce rapid heart action.

At a later period in the patient's life comes the final onset in cardiac syphilis, and according to my obser-

Fig. 4 (case 2).—Low power magnification showing large island of lymphocytes and fibroblasts in degenerated area of involved muscle.

vations it is characterized by a precipitate cardiac insufficiency, characterized by shortness of breath, edema of the extremities of a mild degree, and cardiac pain, which may be quite severe and may radiate down one or both arms so that angina pectoris may be simulated. However, pain may be entirely absent, and the outstanding features of the illness are those of the enlarged heart with diminished cardiac power. Usually these

metrial growth, indicating the presence of an inherent lack of uterine responsiveness to the substance.

Fifteen of the twenty-three patients with secondary amenorrhea were given 10,000 rat units of estradiol benzoate hypodermically at intervals of four days for from two to four months. All but one menstruated almost cyclically during the period of treatment. Only three, or 20 per cent, of the group of fifteen continued to menstruate regularly after withdrawal of treatment for a follow-up period averaging one year.

Eight patients were given massive doses of from 70,000 to 100,000 rat units of the substance three times in the course of one week of the month for two or three consecutive months. Uterine bleeding, clinically indistinguishable from the normal, followed in each instance within two weeks after the last of the triweekly injections. One patient conceived during the month following the second course of treatment and bore a healthy child, and two of the remaining seven patients have been menstruating regularly during a follow-up period of seven months. The remaining five patients have lapsed into their former state of amenorrhea.

It is evident from this study that the administration of large doses of estrogen, employed as the sole agent in the treatment of amenorrhea, yields about 20 per cent cures and that short courses of massive doses (300,000 rat units in three divided doses) repeated monthly are probably more effective than continuous treatment with the substance.

#### EFFECT ON HYPOMENORRHEA

Hypomenorrhea (regular but short and scanty menstruation) is often a precursor of amenorrhea. Two of six hypomenorrheic women who had taken daily from 225 to 1,200 rat units of estriol either as theol itself or as its combined form, emmenin, and three of eight additional patients who had received parenterally from 5,000 to 10,000 rat units of estradiol benzoate at intervals of four days for approximately three months have been menstruating normally during a follow-up period averaging fifteen months.

Two of the three cured patients in the latter group were subjected to premenstrual curettages before and after treatment. In both there was a conversion of an atrophic endometrium into a normal premenstrual pattern—a phenomenon which Kaufmann<sup>29</sup> also observed with the use of substitution treatment. These observations justify the assumption that the hypomenorrhea in these two patients was mainly due to lack of uterine response, which was corrected by the administration of estrogen.

#### EFFECT ON PRIMARY DYSMENORRHEA

This phase of our study on the clinical uses of estrogenic substances was recently reported by one of us.<sup>32</sup> It was shown that only one of sixteen patients benefited from daily administration of 225 rat units of estriol in combined form (emmenin) daily for periods averaging four months. Large doses, such as from 5,000 to 10,000 rat units of estradiol benzoate given hypodermically every fourth day over a period of from three to four months, produced no effect in three of thirteen patients and complete relief during the course of treatment in the remaining ten patients.

An analysis of the foregoing data on the treatment of amenorrhea, hypomenorrhea and dysmenorrhea with large doses of estrogen permits the conclusion that the

resultant correction of the associated uterine atrophy produces temporary relief of the respective symptoms. Permanent relief is relatively rare and occurs only in instances in which the uterine atrophy is merely the residuum of a previously existing ovarian deficiency which, in the course of time, was corrected either spontaneously or through the mediation of other measures acting directly on the pituitary-ovarian mechanism. Estrogen is, nevertheless, a valuable adjunct to other remedial agents in the management of these conditions.

#### EFFECT ON FERTILITY

It is reasonable to assume that relatively small doses of estrogen—purely a substitutive quantity—can have no deleterious effect on fertility. What harmful effects, if any, do massive doses produce? It is premature to answer this question. However, four of our patients who had received from 30,000 to 430,000 rat units of estradiol benzoate in the course of from one to two months for the relief of amenorrhea or hypomenorrhea conceived soon after withdrawal of treatment. Two of the four were delivered of healthy offspring; the other two have not yet reached full term of pregnancy. When one recollects the increasingly high concentration of the substance normally present in the blood during advanced pregnancy (approximately 1 mouse unit per cubic centimeter), it is difficult to concede more than temporary pituitary-ovarian inhibition from the administration of large doses of the substance.

#### EFFECT ON THE SEVERE MENOPAUSAL SYNDROME

The most impressive results with the use of estrogen are obtained in patients suffering from severe symptoms of the artificial or natural menopause. This phase of our study on the clinical uses of estrogens was reported in a recent publication.<sup>33</sup>

Only large doses, quantities producing a definite hyperestrinemia, are effective in inhibiting the hyperfunctional state of the anterior pituitary lobe current in this condition. As emphasized by us<sup>33</sup> and corroborated by Albright<sup>17</sup> and Frank,<sup>34</sup> amelioration of the symptoms is concomitant with a definite decrease in production of the gonadotropic factor of the hypophysis. Our best results were obtained with the use of 10,000 rat units of estradiol benzoate given hypodermically every fourth day until the major symptoms had subsided. Withdrawal of treatment at this juncture almost invariably resulted in recurrence of the symptoms. We have therefore continued treatment with gradually reduced doses for a period of from four to six months, in order to accustom the economy to function on minimal doses or on none at all.

We have thus far followed up, for an average period of thirteen months, fifty-one patients who received the full course of treatment. Twenty reported complete relief of symptoms, twelve experienced a return of some symptoms after four or five months, fourteen were relieved only during treatment, and the remaining five were unrelieved even during the administration of the substance. The associated diabetes mellitus of three patients was totally controlled without insulin as long as they received 2,000 or more rat units of the substance every fourth day. On smaller doses the hyperglycemia and glycosuria reappeared.

The left heart wall was distinctly thickened and hypertrophied.

The aorta, at the base of its leaflets, measured 8 cm. and was moderately dilated. About and just posterior to the leaflets there was noted a bluish roughening and swelling, edema and a tendency to minute corrugation of the wall. The coronaries showed ostial narrowing and a roughening and swelling very indicative of syphilis. The coronary change also had a slight

Fig. 7 (case 3).—Gross appearance of heart, showing large open necrotic aneurysmal cavity in heart wall. Aorta practically not damaged.

yellow atheroma of a moderate degree and the more extensive syphilitic involvement was in the first part of the coronaries.

Microscopic study of the heart made from the infected area showed a diffuse inflammatory process within and between the muscle fibers, characterized by numerous aggregations of densely packed lymphocytic cells, plasma cells, occasional eosinophils and innumerable fibroblasts, and a large supply of newly forming blood vessels. Acid-fast stains on these sections failed to reveal tubercle bacilli, and Dr. C. V. Weller of Ann Arbor, Mich., stated that in his opinion the process was syphilitic; he found spirochetes in sections from this heart.

The coronaries showed a thickening of the intima by proliferation and hyaline changes. There were also lymphocytes in the vessel adventitia.

CASE 2.—E. H., a Negro, aged 45, a laborer, admitted to the hospital Feb. 21, 1934, complained of shortness of breath and precordial pain.

February 6, while working, the patient had a sharp left axillary pain, which radiated to the elbow and scapula and in a few moments concentrated in the precordium, where it remained. Thirty minutes later he was weak, and "shortness of breath" developed. That night the dyspnea and pain returned again quite severely. He tried to work the following day but could not do so on account of cardiac pain and weakness. February 13 severe dyspnea and cardiac pain recurred, associated with palpitation and dizziness. February 19 he began to have edema of the extremities.

On physical examination the patient was well developed and well nourished and was at rest, elevated in bed, in a state of moderate dyspnea. The temperature was 98 F., pulse 114, respiration 28, blood pressure 150 systolic, 50 diastolic. The essential informative changes were confined to the chest and heart. The chest expansion was equal on the two sides. Râles

were heard in both lungs. The heart was enlarged 12 cm. to the left and 4 cm. to the right. The apex beat was thrusting and diffuse. Auscultation revealed a to and fro murmur just to the left of the sternum. The rate was regular but quite fast and of the Corrigan type. Otherwise of importance, the patient had an enlarged liver, an enlargement of the lymphatic glands and an edema of the lower extremities. He also had a secondary anemia (hemoglobin 60 per cent), a trace of albumin in the urine with casts, and a four plus blood Wassermann reaction. The blood chemistry was normal.

At necropsy the heart was enlarged and hypertrophied and weighed 600 Gm. The wall of the left side of the heart measured 2 cm. The muscle showed diffuse grayish yellow areas. The aorta was smooth except for slight wrinkling, but unquestionably there was a syphilitic process about the left coronary artery ostium and the basal part of the aorta, where a swelling, edema and bluish discoloration of the intima were noted. At an area within the auriculoventricular septum, and partly extending around the aorta, there was a cavity in the muscle that had two sacculations, one above the other. One of these measured 4 by 2.5 cm. and the other 4 by 3.5 cm. in diameter. They had shaggy, irregular, wrinkled walls and were filled with seminecrotic hemorrhagic material. The coronaries were both narrowed at the ostia and neither of the sacculations communicated with a coronary artery. The entire process seemed to have spread directly from the aorta. Spirochetes were found by Dr. Weller in the heart, and the usual areas of lymphocytes, plasma cells and new blood vessels admixed about necrotic areas were found to be present.

CASE 3.—F. M. J., a Negress, aged 27, was admitted to the hospital Feb. 23, 1935, with a complaint of dyspnea and edema of the feet.

For the past two years she had had shortness of breath and swollen feet. For one year she had noted that the abdomen

Fig. 8 (case 3).—Section showing infiltrating lymphocytes in area of scar tissue.

was swollen. At four o'clock on the afternoon of admission she complained of numbness of the left side of the body, but it was not paralyzed. However, she talked only with difficulty. She made no complaint of cardiac pain at this time.

The physical examination revealed a poorly developed, emaciated body with suggestive skin lesions of pellagra. The temperature was 101, pulse 123, blood pressure 144 systolic, 94 diastolic. Her heart was enlarged slightly to the left. At

## ABSTRACT OF DISCUSSION

DR. J. P. PRATT, Detroit: Much of the confusion in endocrinology is due to the failure to develop and recognize standards. The authors are to be commended for their effort to establish a standard for the utilization of the estrogenic substances. Another commendable effort is their demonstration of the effectiveness of the various estrogenic principles when administered orally. The usefulness of theelin (estrone) has been restricted because administration has been limited to injections. Oil as a vehicle for theelin sometimes causes unpleasant reactions because it acts as a foreign body. Furthermore, the inconvenience of frequent office calls for injections can be eliminated if theelin can be satisfactorily used orally. As criteria for judging the effectiveness of estrogenic substances, objective signs in the treatment of vaginitis and bleeding from the nipples are mentioned. The value of these concrete symptoms may well be contrasted with the vague subjective symptoms of the menopause, which are favorably influenced by a great number of therapeutic agents, the most effective of which is psychotherapy. Subjective symptoms are not satisfactory criteria for standardization. When a measured amount of estrogen given by mouth yields a measurable amount of theelin in the urine, the ability of the body to break down and excrete the hormone can be estimated. This cannot be interpreted, however, as measuring the potency of the hormone. There is apparently variation in susceptibility among different individuals and in the same individual at different times. Nevertheless the average excretion rate and amount taken from a large number of individuals may serve as a useful basis in judging dosage. Final judgment of the effectiveness of the principles must be made from the objective changes in the individual receiving them, just as the required amount of anesthetic, sedative or stimulant is determined.

DR. MARGUERITE S. WILLIAMS, Tucson, Ariz.: I wish to ask whether the authors have used this material in an endeavor to relieve the pain and hasten the process of drying up breasts when it was necessary to wean a baby.

DR. ELMER L. SEVRINGHAUS, Madison, Wis.: The differences between various products obviously cannot be interpreted as differences in absorption, because some of the curves are based on the hypodermic administration of the different materials. Therefore it leaves the question open as to whether part of this material is destroyed or permanently stored within the body, because from the data that were shown in a hasty survey far from 100 per cent recovery was indicated within a week or so after the administration of these larger doses. I think that point needs some attention in the interpretation of this sort of work. I should like further to amplify Dr. Pratt's comments by asking whether the authors have attempted a correlation of the perfection of control of the menopause with the size of the doses employed. Were the larger doses any more successful in control than the smaller doses, or, conversely, were doses just adequate to control the menopause still inadequate to keep up the urine and blood concentration to somewhere near the normal level?

DR. LEONARD G. ROWNTREE, Philadelphia: I wish to say a word of appreciation for the clinical investigation the authors have been carrying on in the last few years. I have had the opportunity of watching them at work. I admire both the way they planned and carried out their clinical investigation in the field of gonorrheal vaginitis in children. When one considers the terrific difficulty that has surrounded the control of this terrible affliction of children in times gone by and the immediate control within eight weeks, which will be permanent if treatment is continued, by the administration of theelin, it represents real advance. If theelin had accomplished nothing else in the field of therapeutics, it would have been worth all the time and effort that has been expended in its development.

DR. CHAUNCEY D. LEAKE, San Francisco: This is an admirable discussion of the clinical measurement of what is no longer a crude drug but a definite chemical agent. I would therefore suggest that in the use of a definite chemical agent such as theelin (estrone) or theelol (estriol) it might be better to express dosage of that agent in terms of milligrams rather than in terms of rat units. The situation is quite comparable to such a proposition as prescribing morphine in terms of pain-relieving units; no one does that. One should remember,

of course, that bio-assay is merely a method of estimating chemical concentration by means of a biologic end point. It is true that one can estimate the estrogenic substances as they occur in the blood or urine only by a biologic method and then one has to express the concentration in rat units. But when one is administering a definite chemical agent in crystalline form I think it would be preferable for the purpose of scientific standardization in clinical work to give it in milligram dosage.

DR. CHARLES MAZER, Philadelphia: The several estrogenic substances employed in our experimental work were of necessity standardized biologically in our laboratory by the Allen-Doisy method, since we had no means of determining their relative values on the basis of the international unit. The international unit, which is 0.1 microgram, varies widely with the product employed. Thus, for instance, 1 Gm. of estradiol yields 6,500,000 rat units, as compared with the 1,000,000 rat units which a gram of theelin yields. I was able to read only part of the paper, the contents of which cover most of the questions raised in the discussion. May I, however, emphasize the importance of employing massive doses, such as 10,000 rat units every fourth day, in conditions such as the severe menopausal syndrome wherein inhibition of anterior pituitary lobe activity is the objective. Usually there is a subsidence of the major symptoms of the menopause within a month or six weeks. Gradually reduced doses can then be given until the patient becomes accustomed to function normally on minimal doses or on none at all. The advisability of employing large doses of estrogenic substance in suppressing milk secretion at the time of weaning the infant is doubtful not only because of the high cost of the product but also because of the ease with which this is accomplished by the usual methods. In some cases of abnormal milk secretion (galactorrhea) the use of large doses of estrogenic substance was found to be effective.

SYPHILIS OF THE MYOCARDIUM  
AND CORONARY ARTERIES

JACK C. NORRIS, M.D.

ATLANTA, GA.

Syphilitic infection of the myocardium has been observed for more than a hundred years. The hearts most often described were those in which gummas were present. Little thought was given to the interstitial tissue changes until the years 1866 to 1894. In 1927 reports were made which indicated that myocardial syphilis is of rare occurrence, and some investigators have intimated that the myocardium is never affected by syphilis. Varied opinions and observations made by excellent pathologists have therefore given rise to considerable controversy concerning the disease.

According to Conner,<sup>1</sup> who has recently published an excellent summary of the development of the knowledge concerning cardiovascular syphilis, Morgagni, in his dissections of syphilitic bodies during his lifetime (1682-1771), observed syphilis of the heart, pericardium, aorta and other arteries. In a woman, aged 22, he observed ulceration of both ventricles. Conner refers further to Ricord, who in 1845 first found a gummatous mass in the heart wall with an associated thickening of the endocardium and likewise mentions the fact that Virchow in 1858 found a similar case of syphilis of the heart. Saphir<sup>2</sup> made a careful historical review of the subject and mentions

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the author's reprints.

Read before the Section on Pathology and Physiology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

1. Conner, L. A.: Development of Knowledge Concerning Role of Syphilis in Cardiovascular Disease, J. A. M. A. 102: 575-581 (Feb. 24) 1934.

2. Saphir, Otto: Syphilitic Myocarditis, Arch. Path. 13: 266 (Feb.), 436 (March) 1932.

decidedly that aside from the occasional gumma of the myocardium the only cardiovascular syphilis is that which affects the aortic orifice and aorta with involvement of ostia of the coronary arteries. I have not been convinced that interstitial changes in the myocardium can be produced by the spirochetes. Certainly many investigators have repeatedly failed to demonstrate the spirochetes in the myocardial lesions. The feeling of the pathology department is that the interstitial changes are secondary to the myocardial ischemia resulting from the coronary orifice involvement and are not inflammatory in origin. My own study on the coronary arteries convinces me that syphilis plays no part in coronary disease. In going over several hundred autopsies in which there was occlusive coronary disease, the incidence of syphilitic aortic involvement was very low (approximately the same as that of the general autopsy material). Again, the most common structural bases for angina pectoris is coronary disease, and there are a number of clinical studies which show that the incidence of a positive serologic reaction in angina pectoris is no higher than that of the general population.

DR. HENRY C. SWEANY, Chicago: I want to ask Dr. Norris if any extensive attempts have been made to culture other micro-organisms from the lesions he has described.

DR. JACK CLAYTON NORRIS, Atlanta, Ga.: I know that I am dealing with a controversial subject. I approve of everything that has been said concerning the treatment. The speakers follow very much the program I do in these cases. I do not give arsenicals. I did make every attempt to find other organisms to explain these lesions and could not do so. Everything was excluded and the patients had all the histologic, serologic and bacteriologic principles confirmed, with the added finding of the spirochetes in the hearts. Heart syphilis does occur, and one may have a patient die from a syphilitic myocarditis and think that he has had something else.

## INTRAPLEURAL PNEUMOLYSIS IN CLOSING TUBERCULOUS CAVITATION

### INDICATIONS AND LIMITATIONS

GEORGE L. STIVERS, M.D.

Medical Director, Fall River General Hospital  
FALL RIVER, MASS.

The closure of a tuberculous cavitation by the elimination of pleuropulmonary adhesions necessitates a complete study of the intrathoracic cavity by intrapleural thoracoscopy. Thoracoscopy visualizes the contents of the pneumothorax cavity in the living subject

### Average Results of Compression in One Hundred Cases of Artificial Pneumothorax

- 10 cases—complete collapse—satisfactory
- 10 cases—selective collapse—satisfactory
- 20 cases—partial collapse—eventually may be satisfactory
- 20 cases—incomplete collapse—unsatisfactory—pneumothorax given only to prolong life
- 15 cases—unsatisfactory collapse—unsuitable for intrapleural pneumolysis—other surgery indicated (25 cases, provisionally accepted for pneumolysis)
- 3 cases—accepted for intrapleural pneumolysis but found unsuitable at time of thoracoscopy
- 22 cases—declared appropriate by thoracoscopy for intrapleural pneumolysis

and defines the anatomy of the lung and chest wall with a richness of true color that is distinctive. These studies are illustrated by reproductions from actual pictures taken at the time of thoracoscopy. My discourse will be confined to a few significant indications, which, occurring during the course of pneumothorax therapy, suggest the employment of intrapleural pneumolysis.

As a preliminary study I shall consider the average results of compression in 100 cases of artificial pneumothorax in which some degree of collapse has been obtained. A complete collapse is established in approximately ten of these 100 cases. A selective collapse of the diseased area giving satisfactory results may be attained in another ten cases so treated. As a result of

Fig. 1 (B. M. L.)—Anteroposterior (A) and lateral (B) views. The lung is held to the chest wall by many adhesions.

pleural adhesions that unite the lung and chest wall, eighty cases remain in which lung collapse is ineffectual. It should be emphasized that not all these patients are potential subjects for intrapleural pneumolysis. Twenty of these eighty cases may be classified as a group in which, by continuous cautious pneumothorax therapy, a satisfactory partial collapse may be brought about. Another twenty cases will show by roentgenologic examination the pathologic process so far advanced or so complicated that therapeutic pneumothorax is given only to prolong life.

Fig. 2 (B. M. L.)—Thoracoscopic picture of an old lung, pigmented with eight adhesions to the chest wall.

Forty cases remain, therefore, in which pleuropulmonary adhesions constitute mechanical obstruction that prohibit, even with the most careful pneumothorax technic, a satisfactory closure of cavitation. These patients are referred to the thoracic surgeon as possible subjects for intrapleural pneumolysis. This does not

Owing to lack of space this article is abbreviated here. The complete article appears in the author's reprints.  
Read before the Section on Surgery, General and Abdominal, at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

Careful study will therefore reveal that from 10 to 20 per cent of aortic syphilitic patients have involved muscles; yet this figure, as I have previously stated, is a low index of incidence and with more complete investigation it is believed that every patient with aortic syphilis will also be found to have myocardial syphilis. However, at this time I cannot positively substantiate this opinion with accurate observations.

Fig. 1 (case 1).—Gross appearance of heart, showing gray-white area of syphilis in myocardium.

Many writers seem to think that muscle involvement depends largely on aortic damage and Paullin<sup>9</sup> feels that coronary narrowing encourages muscle lesions to occur because of nutritive interference. His thought fits in well with the impression that all patients with aortic syphilis have an associated myocarditis. Recently, several reports have been made of mitral valve syphilis, which I have never seen at necropsy. Blackman<sup>13</sup> reported two such cases, one of which seems a classic type. His patients had aortic and mitral insufficiency and he traced the involvement by histologic methods to the mitral valve.

He found syphilitic infiltration in the intraventricular and the membranous septums. This observation is of importance in that it gives rise to etiologic speculation: if the infiltration spreads from the aortic lesions into the intraventricular septum, why could it not infiltrate into other areas of the heart?

Based on a careful study of the postmortem examinations of fifty patients with syphilitic heart disease, I<sup>16</sup> found that, out of twenty-four who had primary chancres, cardiovascular symptoms with incompetence occurred most often seven years after the occurrence of the primary lesion.

#### GENERAL GROSS PATHOLOGIC CHANGES

As a rule syphilitic hearts are enlarged by hypertrophy and dilatation and have an average weight of 570 Gm. each. Externally they often have a pink-red, bronze color. As a rule the muscle is moderately soft and does not have the firm resistant feel and appearance of the hypertensive heart. The auricles are usually thin, roughened and dilated. The epicardium occasionally is covered with thin, pink, edematous adhesions but never has the shaggy, exudative adhesions of the more common types of pericarditis. Incision into the muscle usually reveals a thin wall from 2 to 2.5 cm. in thickness. The typical syphilitic processes in the muscle are most often seen in the wall of the left side of the heart, somewhere near the base, and are recognized as gray-yellow or gray-white, variably sized, irregular areas, usually not surrounded by hyperemic zones but well defined in type, and which gradually merge into the adjacent tissues. The gray or yellow spots may be quite extensive and numerous, or, on the other hand, only one circumscribed area of involvement may be found. Occasionally there is a diffuse involvement with areas of a lighter nature causing the ventricular muscle to have a mottled appearance. The endocardium may be white and definitely thickened. As a rule, fibrous tissue streaks may also be seen. The intraventricular septum muscle is often involved. Occasionally, as illus-

Fig. 2 (case 1).—Section showing lymphocytes and other cells in muscle between fibers, with many destroyed muscle cells.

trated in this paper, bizarre muscle damage of an aneurysmal nature may occur in syphilitic myocarditis, and large myolytic cavitations with irregular, hemorrhagic, degenerated yet well defined walls may be present. Two such unusual hearts have been observed.

When the aorta is involved, elevation, nodulation, corrugation and wrinkling of the intima at the aortic

operation and that no serious involvement of other organs is present to hinder the patient's ultimate recovery.

Conversely, factors such as lung tissue and blood vessels in adhesions, noninterfering or flaccid adhesions, marked flexibility of the mediastinum, advanced contralateral lung infections and chronic empyema are contraindicative.

Fig. 7 (L. H.).—Two adhesions easily diagnosed roentgenographically.

nated. This procedure is not essential and, in fact, may constitute an element of danger. In my work I have refrained from cutting adhesions that do not exert a restraining influence, because of the possibility of unavoidable complications.

Fig. 8 (L. H.).—Thoracoscopic study of the two adhesions in figure 7, with a picture of an early disease.

#### ASSOCIATION OF THE ROENTGEN WITH THE THORACOSCOPIC STUDY

Fluoroscopy and a study of the stereoroentgenogram, in the majority of cases, will indicate that closure of cavitation depends on the removal of one or more adhesions that prevent satisfactory collapse.

Roentgenology should always be considered a valuable aid in the interpretation of pleuropulmonary adhesions but seldom will establish accurately the size and

contents of the adhesions. However, it will determine the most suitable location for the introduction of the thoracoscope.

To illustrate the association of the roentgen with the thoracoscopic study, I present figures 4, 5 and 6.

The actual conditions within the thoracic cavity, as viewed by the thoracoscope, frequently differ from those shown on the x-ray film. Favorable operative work may be accomplished in spite of an adverse roentgenologic appearance.

There are many cases that apparently conform to all indications for intrapleural pneumolysis, yet thoracoscopy will reveal them unsuitable for operation. Viewing the adherent lung and knowing that intrapleural pneumolysis would be of no avail will satisfy the operator that the procedure of thoracoplasty should be adopted.

#### DURATION OF THE PULMONARY DISEASE

The duration of the disease may be determined roughly by a correlated study of the history, the stereo-

Fig. 9 (J. McD.).—Adhesion to the lateral chest wall.

roentgenograms and serial films and the thoracoscopic abnormalities.

In early cases in which the duration of the disease is estimated at less than two years the adhesions, if severed within three to six months after the initial pneumothorax, will be found to consist of soft connective tissue, white or pale red, quite freely

movable and containing only a few small blood vessels. They may be severed without difficulty. An example of early disease is shown in figures 7 and 8.

When the pulmonary disease is of longer duration than two years, the adhesions are more organized, firm to the touch, usually short, round or fan shaped, cover considerable rib surface and frequently contain large blood vessels and lung tissue. Figures 9, 10 and 11 are examples of old pulmonary disease.

#### THE EFFECT OF SEVERING MULTIPLE ADHESIONS

When many adhesions retard the closure of a large cavity and all are severed at one operation, the effect of this sudden complete compression of the lung may occasion bronchiogenic spread into the contralateral lung. A two or three stage operation is the preferred surgical technic. An example is shown on the roentgenograms reproduced in figure 12.

It is impossible to prognosticate with certainty the suitability of adhesions for severance until thoracoscopy is performed. The technical success of intrapleural pneumolysis will often depend on further observation, which is possible only as the operation proceeds.

#### THE EFFECT OF TENSION ON ADHESIONS

The presence of adhesions alone is not an indication for intrapleural pneumolysis unless there is positive assurance that tension is present and that closure of cavitation is prevented by the stress exerted on the cavity wall. In cases in which cavitation is not present

patients have increased heart rates, most often from about 90 to 100 beats per minute, and without fail they also have variable cardiac irregularities which are described as palpitating, flooding or skipping beats of the heart with pulses of poor volume. Auscultation will frequently reveal the presence of soft distant systolic murmurs, with the beating heart action fairly

Fig. 5 (case 2).—Oil immersion study of lymphocyte and plasma cells.

slow and regular, and then suddenly the rate may change and the heart action becomes quite fast and irregular. On one or more occasions fibrillation has been observed, and heart block has been encountered. Following the deficiency in muscular power and the disturbed heart action comes the final failure, usually within two years from the onset, and the feet become edematous and general anasarca results. Congestion of the liver, spleen, lungs and other tissues occurs, and death follows in short order, frequently caused by a terminal pneumonia or angina, or sudden cardiac failure, presumably of heart dilatation. Other causes of death have been seen, such as pulmonary thrombosis, coronary occlusion or rupture of an aortic valve.

To summarize, one should suspect myocardial syphilis whenever a young person with syphilis complains of cardiac pain and irregular heart action and a fast irregular pulse, with an inability to meet his physical demands as he formerly met them; who has an enlarged heart and a normal or slightly elevated blood pressure, with soft systolic murmurs and diminished muscular heart tones, and whose story fails to reveal any other cause for his cardiac indisposition.

It is not my intention at this time to give a complete differential study of myocardial syphilis from that of other heart diseases, yet it is proper to remember that the disease is most often confused with hypertensive, arteriosclerotic and rheumatic heart maladies.

The following new cases are presented:

CASE 1.—A. M. M., a Negress, aged 42, admitted to the hospital Sept. 22, 1933, complained of shortness of breath.

She had had no other serious complaint until September 14, at which time she began to have palpitation of the heart after eating. Twenty-four hours later the palpitation returned accompanied by "shortness of breath," with a feeling of constriction about the heart. A few days later all her symptoms had become progressively worse with the added discomforts of vertigo and dizziness. Three days before admission she noted a very distinct dyspnea with a very rapid action of the heart.

Physical examination revealed that the patient was well developed and in a state of mild dyspnea. The temperature was 97, pulse 60-120, respiration 24, blood pressure 160 systolic, 92 diastolic. The head, neck, eyes, thyroid and mouth were essentially normal. Pulses were irregular in rate and rhythm. The lungs were normal except for mild congestion.

The heart was apparently normal in size, but it was quite irregular in rhythm and rate, beating slowly for a few minutes and then increasing its rate quickly to from 100 to 120 beats per minute. The heart tones were of poor muscular quality and no murmurs were heard by auscultation.

The first hospital day she had only moderate dyspnea, and on the second a fever of 101 F. was charted. On the morning of the third day, after three days of irregular heart action, she died suddenly.

The necropsy revealed the pericardium to contain about 100 cc. of a straw colored fluid. The heart weighed 425 Gm. and was a pinkish bronze that was reflected through a considerable quantity of yellow epicardial fat. The muscle was rather firm to the feel but was pale. At a point just below the left auricle

Fig. 6.—Different forms of spirochetes that are found in syphilis of the heart. Upper left, organisms from valve lesion. Upper right, from case 1. Lower left, from heart in case 2.

there was seen a peculiar grayish, slightly roughened, nodular area of degeneration, about 4.5 by 3 cm., which had caused extensive muscle damage. Cutting through the heart wall at this point, the grayish inflammatory area extended from the epicardial surface deep into the musculature, where it was surrounded by a faint marginal zone. This zone was not like that seen in coronary occlusion, in that the grayish inflammatory process was firm and merged gradually into the deeper muscle. No other such areas of inflammation were seen.

involved lobe or lung, the sputum will become negative in 90 per cent of the cases and there will be no fever and gain in weight in over 80 per cent; whereas if the pneumothorax is partial only 15 per cent will become sputum negative, 33 per cent will become afebrile, and there will be weight gain in only 57 per cent. One can well understand, therefore, the necessity of obtaining a

Fig. 17 (E. G.).—Thoracoscopic study showing caseous exudate on the adhesion and on the lung surface.

thoroughly satisfactory pneumothorax. In that group of cases of partial pneumothorax so well described by Dr. Stivers, internal pneumolysis is the best and most direct method of attack. I would emphasize that each case must be considered on its merits. The mere presence of adhesions is not of itself an indication

Fig. 18 (A. L.).—Thoracoscopic study of fibrinous exudate.

for operation, for the procedure is not warranted in the presence of advanced bilateral lung tuberculosis or advanced extrapulmonary lesions. Also the partial pneumothorax must be of sufficient size to allow manipulation of the instruments. The operation itself requires infinite patience and delicacy of detail. It may be necessary to repeat the procedure. This applies particularly to the short, broad adhesions. After partial division, an intervening period of continued pneumothorax may better

define and stretch the pleural bands. The chief complications are, first, hemorrhage. This should not be troublesome if one studies the adhesion carefully, thereby avoiding large vessels, for the small ones that are encountered in the adhesions themselves can be readily controlled with the electrode. Second, fluid sometimes appears following the procedure. Usually this is thin and is soon absorbed.

DR. VICTOR STRONG RANDOLPH, Phoenix, Ariz.: The percentage of patients to be operated on, as Dr. Stivers has given it represents his own series. The percentage of pneumothorax cases requiring an operation varies with the individual surgeon, and with surgeons and internists. The author's figures are in the general scope. Dr. Cutler, who has an exhibit here on the same subject, estimates his percentages at somewhat different levels. I want to emphasize again what Dr. Stivers said about the indications. They are the same as those for artificial pneumothorax; namely, a cavity which fails to collapse. The value of complete or adequate pneumothorax after closure of the cavity is represented in the case that has been continued under pneumothorax after cutting of the adhesions, until the lung has had an opportunity to heal. Many of these cases after healing and reexpansion of the lung will not indicate on the x-ray film very much evidence of their former trouble and

Fig. 19 (J. F.).—Thoracoscopic study showing the necrotic effect of marked tension on the adhesion.

these patients may look forward to relatively normal lives. In a case in which I operated in 1929 the adhesions were cut, the cavity was closed and healed, the lung reexpanded, and the young woman has since gone through pregnancy safely. I wish to qualify somewhat the statements of the author with regard to extensive contralateral involvement. I believe that one of the most important uses of intrapleural pneumolysis is in the cases of bilateral disease in which bilateral pneumothorax may with safety be established and the two lungs treated at the same time or in some cases consecutively. In four such cases I have been successful in cutting adhesions on both sides and in two of these the lungs have since reexpanded and the patients are well. One has been working for about three years. In other cases adhesions have been cut on one side and it has been found not necessary to cut any adhesions on the opposite side. The operation of cutting adhesions offers great possibilities for cure of advanced cases of bilateral disease.

DR. GEORGE L. STIVERS, Fall River, Mass.: Bilateral disease is present in a great many cases of pulmonary tuberculosis. I have found in bilateral disease, with one lung under compression, that, if I attempt to do a pneumolysis on that one side, in about 10 per cent of the cases extension of the disease on the contralateral side will take place. If a minimum amount of disease is present on that side, in a short while, two or three

the apex there was heard a systolic murmur and a gallop rhythm, with sounds of poor muscular quality. The heart rate was quite rapid.

Because of sparse information charted during her final illness, her record in the outpatient department was found and it was observed that during a visit to the clinic in 1933 she complained of slight dyspnea and swelling of the feet. She also had drunk one pint of whisky daily and reported two stillbirths and one miscarriage. Her blood pressure was normal (135 systolic, 90 diastolic) and her blood Wassermann reaction was four plus.

No description of her death was available other than that she died quietly in bed after a short period of groaning, on the day following admission.

The necropsy showed the heart to be enlarged and hypertrophied on both the right and the left side. It weighed 580 Gm. The tricuspid and mitral valves were normal except for a slight thickening near the aortic basal septum. The aortic valves were normal. The coronary arteries were slightly narrowed at the ostia, with a slightly further narrowing as the artery proceeded downward. The base of the aorta showed a slight wrinkling of the intima. Just below the aorta, on the left side of the heart at a point on a line with the auriculoventricular junction, there was found a saccular cavitation, which tended to dig deep into the heart muscle and to extend behind the aorta. The process measured 4 by 2 by 6 cm. It had a communication with the mitral cavity through a small (1 cm.) opening. This cavity was irregular, ragged, puckered, swollen, thick and glistening except at points where it tended to be thrown in folds. It contained old clotted blood. It did not communicate with the coronary arteries. The muscle throughout the heart had yellow-gray areas in it. Spirochetes were found in the heart by Dr. Weller.

#### COMMENT

These three cases presented normal blood pressures. The type of lesions involving each heart are of particular interest, because of their rarity, the age of the patient, the absence of causes other than syphilis, and the symptoms caused by such processes. Of further interest is the fact that in each case spirochetes were found to be present. In 3,000 autopsies I have not before seen hearts that had similar syphilitic cavitations in the muscle.

I cannot explain definitely how those lesions occurred. It is thought that the process may be similar to that in the formation of aortic aneurysms in which a syphilitic ulcer attacks the endothelium of the heart wall, destroying the endothelium and finally pursuing its way into the muscle, destroying as it proceeded inward, and eventually ending with an aneurysmal-like process. In neither instance did those sacculations connect with the coronary arteries.

The heart rate and irregularities can be explained satisfactorily by the infiltrations into the intraventricular septums and in the left heart muscle. It is quite reasonable to assume that fibrosis, lymphocytosis and other inflammatory processes of such order might disturb the orderly mechanism of the nerve fibers, so that heart block, auricular fibrillation, gallop rhythm or any of the cardiac irregularities heretofore described might occur.

#### CONCLUSIONS

In a previous report I attempted to summarize my impressions of the problem and stated: "It is evident that syphilitic myocarditis progresses rapidly to serious stages with a decline in cardiac efficiency. The extent of the damage to the muscle will largely influence the train of cardiac irregularities. It is my further impression that myocardial syphilis is seldom, if ever, restored to health, because syphilis in tissues is largely an inflammatory process with degeneration of the structures, and a release of poisonous toxins."

With these thoughts in mind I feel that the problem of cardiac syphilis is one of grave significance. I have

become thoroughly convinced, after long observation, that whatever aid can be eventually offered persons affected with this disease lies in the hope of firmly establishing in the minds of other physicians the fact that in every syphilitic patient, sooner or later, the heart will be fatally damaged unless adequate and suitable treatment is instituted early in the disease with the hope of preventing syphilis from occurring in the heart.

It would be a great step forward toward entirely preventing cardiac syphilis if the syphilologists and other physicians would worry less about the chancre and more about the heart during active syphilis.

810 Doctor's Building.

#### ABSTRACT OF DISCUSSION

DR. JAMES L. DUBROW, Des Moines, Iowa: Having practiced for some time in the South, I agree with Dr. Norris's statement that myocardial syphilis is more common in the Negro than in the white person. However, syphilis respects neither race nor color. About the therapeutics of this disease, I think Dr. Norris is somewhat pessimistic. Patients presenting symptoms and signs of cardiovascular syphilis accompanied by a positive Wassermann reaction and cardiac changes as noted on physical examination and in the electrocardiogram are prone to decompensate early and to develop pleural effusion and anasarca. Death may ensue unless a strict therapeutic regimen is enforced. It is best at first to place these patients at rest in bed and on a low protein salt free diet. Five grains (0.3 Gm.) of potassium chloride in twenty-four hours is given to take the place of the salt. Digitalization should be resorted to at once. It is particularly important when there is anuria, since the latter is not infrequently due to myocardial failure and not to nephritis per se. Large doses of digitalis should be used. Another important step is the removal of accumulated fluid, particularly of effusions into the pleural cavities, since they in themselves increase the cardiac embarrassment. When the cardiac hydrothorax is bilateral, alternate aspiration of each side may be indicated. Left sided cardiac hydrothorax is infrequently encountered when the right pleural cavity has been obliterated by previous adhesions. Laboratory examination of the aspirated fluid may be done when there is any doubt as to the diagnosis. On the other hand, it is less important to remove the fluid from the peritoneal cavity unless it interferes very much with the breathing. Iodobismutol with saligenin may be given intramuscularly later, since it tends to produce a negative Wassermann reaction. When syphilitic aortitis or aneurysm is associated with the myocarditis, arsphenamine should be avoided.

DR. GEORGE R. HERRMANN, Galveston, Texas: It is gratifying to find some one in the South who can present photographic evidence of the spirochetes in myocardial syphilis. The histologic picture is in itself not pathognomonic. I had the pleasure of working in Dr. Warthin's laboratory some years ago. After I gravitated southward I encountered a great deal more cardiovascular syphilis than I had ever seen in the North. Occasionally I ventured clinical diagnosis of myocardial syphilis in the absence of signs of aortic disease but I never succeeded in getting a pathologist to demonstrate the spirochetes. It is possible that the myocardial reaction to the spirochetes destroys the latter in many instances. The picture that is encountered in the absence of aortic disease is not absolutely characteristic from the clinical point of view. The diagnosis can be made practically only by exclusion. Even those among the clinicians who have objected to the diagnosis of myocardial syphilis are now gradually coming to the conclusion that there are cases of acquired myocardial syphilis in which the aortic involvement is minimal. It is not common to find syphilitic coronary disease beyond the very orifice or the intra-aortic part of the coronary arteries according to most pathologists, even Warthin himself.

DR. MORRIS H. NATHANSON, Minneapolis: As regards the possibility of syphilitic involvement of the myocardium and coronary arteries, I wish to state that the department of pathology at the University of Minnesota Medical School feels

may be classified in the genus *Bacteroides* have been isolated from fetid and gangrenous suppurations of practically all organ systems of the human being, as well as from normal mucous membranes."

#### PATHOGENICITY

The *Bacteroides* of feces have not been proved to be pathogenic. However, species isolated from lesions in man have been demonstrated to be pathogenic for laboratory animals. Henthorne, Thompson and Beaver have shown that *Bacteroides funduliformis* produced subcutaneous abscesses in guinea-pigs, and systemic infections as well as abscesses in the liver, lungs and joints in rabbits.

#### CLASSIFICATION

Castellani and Chalmers<sup>14</sup> in 1919 described a large group of anaerobic, nonsporulating bacilli which had not previously been classified systematically under the generic designation "*Bacteroides*." This name was adopted by a committee of the Society of American Bacteriologists and was given a place in its systematic classification as recorded in Bergey's<sup>15</sup> manual of determinative bacteriology. According to the manual, mem-

production of hydrogen sulfide, production of gas from carbohydrate mediums, and hemolytic action on erythrocytes.

#### OCCURRENCE

Veillon and Zuber reported the isolation of anaerobic bacteria in cases of osteo-arthritis of infancy, pulmonary gangrene, otitis, mastoiditis, abscess of the brain, gangrenous angina, dental caries, appendicitis, peritonitis, peri-intestinal phlegmons, Bartholin's, and pelvic suppuration. Some of these anaerobes were cocci, some were gram-positive and some were spore forming, but several gram-negative members of the genus *Bacteroides* were described. Similar organisms have been found in the normal intestinal tract by Distaso<sup>16</sup> and by Debono.<sup>17</sup>

One of the chief contributions of reports from the Mayo Clinic has been the association of infection caused by *Bacteroides funduliformis* with ulcerating necrotic carcinoma (fig. 2). Apparently necrosis and infection provide an ideal habitat for proliferation of *Bacteroides funduliformis*. In all the cases in which death occurred hepatic abscesses were found; in some cases there were multiple, small nodules, in others a conglomerate mass (figs. 3 and 4).

#### REPORT OF CASES

CASE 1.<sup>18</sup>—A man, aged 64, came to the clinic because of mild abdominal cramps, associated with tenesmus, frequent bloody stools and loss of weight, for the previous three months. Proctoscopic examination revealed an annular, freely movable, nonobstructing adenocarcinoma, which involved the posterior wall of the rectum. A roentgenogram revealed polypoidosis of the rectum and rectosigmoid.

Left inguinal colostomy was performed after the usual pre-operative preparation. Convalescence was uneventful until the seventeenth postoperative day, when the temperature rose sharply to 102 F.; the pulse rate was 120 beats per minute. The colon was opened on the sixth day after operation. The fever continued to be of a septic type, the temperature varying from 99 to 102 F. The patient became jaundiced on the twenty-first postoperative day. The value for serum bilirubin varied from 7.9 to 11.5 mg. per hundred cubic centimeters and the van den Bergh reaction was direct; the number of leukocytes ranged from 19,600 to 25,900 per cubic millimeter of blood. On the twenty-second postoperative day, a roentgenogram of the thorax was reported as showing that the right side of the diaphragm reached the level of the fourth rib anteriorly and that infiltration of the right cardiophrenic angle was present. At this time the liver, which was nodular, could be palpated 4 cm. below the costal margin. A foul, watery material was discharged constantly from the rectum during the entire post-operative course. The irregular fever persisted, jaundice deepened, and the patient gradually declined and died on the thirty-eighth day after operation.

At necropsy the colonic stoma was found to be in good condition. The peritoneal cavity contained 2 liters of clear light yellow fluid. A large, ulcerated and infected carcinoma was found in the rectum; metastasis had occurred locally and to the liver, lungs and left adrenal gland. The liver contained many nodules filled with yellow pus, which had a disagreeable, rancid odor. Metastatic nodules elsewhere in the body were not infected.

CASE 2.—A man, aged 58, came to the clinic May 29, 1933, complaining of blood in his stools for the previous ten months, a bearing down sensation in the rectum for four months and a watery diarrhea, with four or five stools a day, for two months. Proctoscopic examination revealed a large annular carcinoma 7 cm. above the anus, which partially obstructed the rectum.

Fig. 1.—The extreme pleomorphism of *Bacteroides funduliformis* a, two-day culture showing "funduliform" or "ball" forms; b, ten-day culture showing filamentous stage in which the organisms may be 100 microns long and composed of segments from 2 to 20 microns long. Slightly reduced from photomicrographs with magnifications of 1,000 (a) and 950 (b) diameters. (After Henthorne, Thompson and Beaver.)

bers of this genus are "Motile and nonmotile rods, without endospores. Show good growth on ordinary culture media; without pigment formation. Obligate anaerobes." The species are described as being normal inhabitants of the intestinal tract of man and as the cause of suppurative and gangrenous infections.

Because of its pleomorphism, *Bacteroides funduliformis* has been given various names by different investigators. In young cultures the organisms assume a coccobacillary form which is also found in abscesses, and because of this form they have been named "funduliform," "ball," "leukocyte" and "thetoid." Later, filaments ranging from 80 to 200 microns are found. The individual filaments are composed of segments from 2 to 20 microns in length (fig. 1). It is possible that other anaerobes described as "Leptothrix" or "Streptothrix" are closely related to *Bacteroides funduliformis*. The biologic characteristics common to all these various organisms are as follows: marked pleomorphism with production of filaments, requirement of animal tissue in culture mediums, production of indole,

18. This case has been briefly reported previously by Dixon, Henthorne and Macy.

mean that forty cases are suitable for intrathoracic surgery or that satisfactory results for all cases are to be anticipated. About fifteen cases will be deducted for various prohibitive reasons. Among these may be mentioned the presence of large fan shaped, large round, or interlocking adhesions shown on the x-ray films, cavity prolongation into the adhesion, some purulent exudate, extensive contralateral pulmonary disease, very flexible mediastinum, or some other serious complication rendering them unsuitable for intrapleural pneumolysis.

There are, in addition, those cases which are found impracticable at the time of operation after the thoracoscope has been introduced into the chest cavity. In my experience this number constituted 13 per cent of those accepted for operation. These rejections were ascribed to the presence of blood vessels, lung tissue or caseous material in the adhesions.

The foregoing summary of cases emphasizes the important fact that the operative field is limited, for

unsatisfactory collapse of diseased pulmonary tissue should be recognized even if cavitation is not evident.

These indications depend, however, on conditions coincident with the administration of artificial pneumothorax, such as continued chest pain, cough and positive sputum, the effectiveness of pulmonary compression, the

Fig. 3 (B. M. L.).—Thoracoscopic study after severing adhesions.

only twenty-two patients out of the original 100 taking pneumothorax appear to be appropriate subjects for intrapleural pneumolysis.

#### THE VALUE OF INTRAPLEURAL PNEUMOLYSIS

The value of intrapleural pneumolysis is questioned by some phthisiologists. To the advocates of intrapleural pneumolysis the operation is life saving. Its opponents, on the other hand, are of the opinion that it is unnecessary and harmful. There are many physicians who fail to recognize the value of a completely satisfactory pneumothorax and believe that intrapleural pneumolysis should be the last surgical procedure contemplated. As reasons for their objections they cite such complications as hemorrhage, empyema, pleural effusion and spontaneous pneumothorax.

#### INDICATIONS FOR INTRAPLEURAL PNEUMOLYSIS

The indications for intrapleural pneumolysis are similar to those advocated for artificial pneumothorax: open cavitation and positive sputum. In addition, the

Fig. 5 (M. G.).—Thoracoscopic study before pneumolysis shows a single string adhesion and one broad fan-shaped adhesion. The edges of the fan-shaped adhesion represent the outside string adhesions seen in the roentgenogram.

location of the cavity with reference to the adhesion, the character and location of the offending adhesions, the presence of serous pleural fluid, and the stability of the mediastinum. One should also consider the dura-

Fig. 6 (M. G.).—Thoracoscopic study showing the result of cutting these adhesions.

tion of the disease, the age of the patient and the length of time artificial pneumothorax has been administered. Those manifestations indicating the necessity for intrapleural pneumolysis are conditional on a reasonable assurance that relief of distressing symptoms together with a satisfactory collapse will be obtained through

day. Two days after the vaccine was administered an exploratory operation was performed through a low midline incision. Spinal anesthesia was employed. Metastasis to the liver was not found. A movable, napkin-ring type of carcinoma was palpated just at the pelvic peritoneal fold. Anterior resection, to be performed later, was decided on. A small, transverse incision was made above the umbilicus and a loop of transverse colon was brought out as a temporary stoma. The colon was opened with the cautery the following morning.

Convalescence was uneventful until the sixteenth day after operation, when the temperature became elevated to 101.8 F. and the pulse increased to 100 beats per minute. The next day the temperature rose to 105 F. and the pulse rate increased to 120 beats per minute. The patient was placed in an oxygen tent because of cyanosis and dyspnea. The rate of respiration increased to forty-eight per minute on the twenty-seventh day and the patient was cyanotic even though he was in the oxygen tent. Bowel movements from the colonic stoma were at first somewhat loose, but otherwise the stoma functioned satisfactorily. From the seventeenth postoperative day on, one or two chills occurred daily, the temperature ranged from 96 to 105 F., and the pulse rate varied from 90 to 170 beats per minute. On the twenty-third day, leukocytes numbered 10,700 and erythrocytes 3,769,000 per cubic millimeter of blood. The differential count revealed the following percentages: lymphocytes 8, monocytes 2 and neutrophils 90. The value for hemoglobin was 12 Gm. per hundred cubic centimeters of blood; the value for the serum bilirubin was 7.9 mg. per hundred cubic centimeters. Slight jaundice was present and a hepatic abscess was suspected. The value for serum bilirubin increased to 10.7 mg. per hundred cubic centimeters on the twenty-fifth day, and two days later the patient was markedly jaundiced. *Bacteroides* septicemia was suspected, although two blood cultures had given negative results. On the twenty-eighth day, *Bacteroides funduliformis* was demonstrated on culture of the blood, although negative results had been obtained on the twenty-sixth day. At times the patient was very anxious and excited. The entire febrile period was characterized by profound, exhausting sweats. The pulse remained unusually strong until the twenty-ninth postoperative day, when the patient failed progressively

Fig. 3.—Section of liver showing localized hepatic abscess.

after the onset of chills and fever. On the twenty-ninth and thirtieth days, 25 cc. of a 1 per cent solution of gentian violet was administered intravenously. The patient died on the thirty-second postoperative day.

At necropsy, multiple abscesses of the liver and lungs, and empyema of the left pleural cavity, were found. Peritonitis was not present. The portal vein contained a septic thrombus.

CASE 6.—A man, aged 53, came to the clinic Jan. 28, 1936, because of alternating periods of diarrhea and constipation and

from three to six bloody stools, which had occurred each day for the previous two months. Jaundice or loss of weight had not occurred. Proctoscopic examination revealed a large fungating growth, beginning 8 cm. above the anus, which involved the left half of the rectum. This growth partially obstructed the lumen of the bowel; it was movable and some infiltration was present. A specimen taken for biopsy revealed adenocarcinoma of grade 2.

Fig. 4.—Section of liver showing multiple hepatic abscesses

January 29, 0.7 cc. of peritonitis vaccine was administered intraperitoneally. Two days later, under spinal anesthesia, an abdominal exploration was performed through a low midline incision. Permanent colostomy and, later, posterior resection of the growth, had been decided on; however, metastasis to the liver had occurred and, because of this, fulguration was deemed advisable. Convalescence was uneventful until the eighth postoperative day, when the temperature became elevated to 100.8 F. where it remained until the tenth day. At this time the patient had a chill and the temperature rose to 105 F. Thereafter, for six days, the temperature was of a septic type and fluctuated daily from 98 to 104.8 F. From the eighteenth to the twenty-fifth days the temperature fell gradually from about 101 F. to 98.6 F., on the day the patient died; the pulse rate varied from 100 to 140 beats per minute. Blood cultures, which were taken on the seventeenth postoperative day, five days later revealed the presence of *Bacteroides funduliformis*. The chills were accompanied by profuse perspiration. On the twelfth day the patient became confused and irrational. His urine was deeply bile stained on the fourteenth day, and the following day jaundice developed. On the twenty-fifth day he became stuporous and his pulse, which had been unusually strong, became weak. He died on the twenty-fifth day, the ultimate outcome having been apparent since the twelfth or thirteenth postoperative day. At necropsy, multiple abscesses were found in the liver. Fulgent thrombosis of the inferior mesenteric vein and abscesses in the left lobe of the prostate gland also were found. Peritonitis was not present.

#### CLINICAL FEATURES

This series of patients included two females and four males. In four of these cases, *Bacteroides funduliformis* septicemia occurred after exploratory laparotomy had been performed for carcinoma of the rectum and in one case it occurred after operation had been performed for carcinoma of the rectosigmoid. In the case in which recovery occurred, *Bacteroides funduliformis* was obtained on culture of material from the wound. Symptoms of bacteremia began on the tenth postoperative day in two cases, on the sixteenth, seventeenth and eighteenth postoperative days in one case each.

The clinical features of *Bacteroides funduliformis* infection naturally depend to a great extent on the organs that are involved. In most of these cases the

but in which tension is shown by x-ray films, it is important to associate adhesions with the various caseous and fibrinous exudates appearing on the parietal and visceral pleurae.

Figures 15 to 18 are examples of tension.

It is my belief that tension on adhesions, in addition to caseous pleural areas, is important in producing pleural fluids and in developing at the insertion of the adhesion on the lung surface small lung perforations or ulcerated areas. In the early case the adhesions are able to withstand considerable stretching, and the lung is spared unnecessary tension. However, in disease of long standing in which the adhesions have become unyielding, the attached lung structure is liable to tear under the force of intrapleural pressure.

The thoracoscopic study (fig. 19) indicates the necrotic effect of marked tension on the adhesion.

In spite of a satisfactory collapse, when thoracoscopy reveals tension with or without cavitation and the disease is of long standing, intrapleural pneumolysis is definitely indicated.

Fig. 10 (J. McD.).—Thoracoscopic study showing pigmented sclerotic lung, with blood vessels in the short round adhesion.

In estimating the degree of cavity closure resulting from intrapleural pneumolysis, one must consider the character of the adhesions, the location of the cavity with reference to the surface of the lung, the texture and thickness of the cavity wall, and the extent of tuberculous involvement.

If all offending adhesions are eliminated by intrapleural pneumolysis, satisfactory collapse will result in the vast majority of cases.

#### SUMMARY

1. About 22 per cent of all cases in which pneumothorax therapy is given are suitable for pneumolysis.
2. To produce satisfactory results it is unnecessary to sever all adhesions present.
3. Intrapleural pneumolysis is a valuable supplement to pneumothorax.
4. The roentgenologic examination does not coincide always with the results of thoracoscopy.
5. The appearance of adhesions and adhesion tension, determined by the thoracoscope, is important in deciding whether intrapleural pneumolysis is indicated.

#### ABSTRACT OF DISCUSSION

FRANK B. BERRY, M.D., New York: Internal pneumolysis is a valuable adjunct to pneumothorax therapy in pulmonary tuberculosis and will convert a partial pneumothorax with a cavity still open into a satisfactory collapse with cavity closure in from 60 to 65 per cent of the cases. The importance of this

Fig. 11 (A. A.).—Thoracoscopic study of old disease showing the adhesions containing lung tissue.

may be made clear by considering what happens to the pneumothorax patient. When a complete pneumothorax is obtained, well over 50 per cent of the patients will eventually return to normal life with negative sputum and the tuberculous process arrested; about 20 per cent will die of the disease. If, however, the pneumothorax is ineffectual and a cavity persists,

Fig. 12 (A. LaM.).—Roentgen appearance of (A) cavity; (B) four adhesions; (C) after cutting three adhesions; (D) after cutting all adhesions.

unless something further is done only about 10 per cent will regain their health and from 50 to 75 per cent will die of tuberculosis. Barnes, in an analysis of 700 cases, goes still further, saying that 85 per cent of patients with open cavities will die within fifteen months if untreated. Furthermore, according to Peyret, if the pneumothorax is complete about the

tized patients have often developed a serious syncope. The prone posture has so bad a reputation that, in some army regulations, moving an anesthetized patient from the dorsal to the prone posture has been strictly forbidden. The danger that accompanies ill advised sur-

gical postures results not alone from circulatory changes, with subsequent depression of heart action and anemia of the brain and medullary centers, but frequently from the effects of the posture on respiratory function.

movements during surgical operations are facts already sufficiently proved.<sup>1</sup> The accuracy of the original observations has been corroborated by independent investigators. Thoracic paralysis under anesthesia has been visually demonstrated by an extensive series of

tracings made with the synchronous pneumograph. This instrument, by applicators encircling the chest at the ensiform level and the abdomen at a point about 4 inches lower, registers on a drum moving at a known rate of speed an independent record of the thoracic and the diaphragmatic movements.

Anesthetic respiratory paralysis becomes vitally significant in upper abdominal surgery when an attempt is made to fix the diaphragm by strong retraction. If the thoracic muscles are completely paralyzed, fixation of the diaphragm must seriously hamper the respiration. Paralysis of the thoracic muscles has been found to be

a valuable sign of the depth of surgical anesthesia.<sup>2</sup> It is now possible to show that thoracic paralysis under anesthesia is at least partly blamable for the serious depression that may accompany operations while the patient is in the prone posture.

Fig. 6.—Upper record, thoracic respiration. Lower record, abdominal respiration. Up stroke, inspiration. Down stroke, expiration. Timer marks ten seconds and minutes. Removal of coccyx. Preliminary barbiturate, nitrous oxide-oxygen anesthesia. Prone posture with supporting pillow. Transfer from dorsal to prone posture with supporting pillow under pelvis. Three minutes of record omitted at X. Note satisfactory maintenance of abdominal breathing in comparison to impeded abdominal movement in figure 5.

When an anesthetized patient is placed lying with the face downward on the firm, flat surface of an operating table the diaphragmatic movements are immediately impeded by the weight of the body resting on the abdomen. The thoracic muscles being paralyzed, the diaphragm attempts to carry on the task of respiratory movement with an effort shown by perceptible lifting of the buttocks with each inspiration. Soon this movement ceases, as the paralyzed thoracic muscles will

months, this disease process will become intensified. I have therefore adopted in bilateral cases the procedure of converting the other side into a pneumothorax, thus producing a bilateral pneumothorax, and after a short period of pneumothorax therapy I eliminate the adhesions on one side. I have found that it is very difficult to control these cases if the spread extends to the contralateral lung. The percentage of cases suitable for pneumolysis varies anywhere from 5 to 45. Matson of Oregon reports 45 per cent suitable for pneumolysis. I believe this rate to be high, and I consider the estimate of 5 or even 10 per cent to be rather low. I think great care should be used in the selection of cases, and I believe that the greatest trouble is doing too much intrathoracic cauterization rather than not enough.

## POSTOPERATIVE BACTEROIDES INFECTION

### REPORT OF SIX CASES

CLAUDE F. DIXON, M.D.  
AND  
JOEL L. DEUTERMAN, M.D.  
Fellow in Surgery, the Mayo Foundation  
ROCHESTER, MINN.

The recent article by Lemierre<sup>1</sup> and the subsequent editorial<sup>2</sup> in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION pointing out the scarcity of reports on postoperative Bacteroides septicemia has prompted us to report six cases of this type of infection. Although the infection has proved fatal in practically all cases which have been reported, it would appear that with a better understanding of the nature of the infection some progress in regard to treatment might be obtained.

At the clinic, infection with *Bacteroides funduliformis* has occurred in six cases in which operations were performed for carcinoma of the large intestine, in two cases in which operations were performed on the male genito-urinary tract, and in one case in which operation was not performed. The six cases in which the infection occurred following operations for carcinoma of the large intestine will form the basis of this report. Organisms with similar cultural characteristics have previously been encountered in blood cultures in other cases, but at the time their significance was not recognized. Since the work at this clinic by Thompson and Beaver,<sup>3</sup> patients who have suggestive complications after operation have been carefully examined for Bacteroides infection.

### HISTORY

Henthorne, Thompson and Beaver<sup>4</sup> recently reported the results of original research on the differentiation and classification of gram-negative bacilli of the genus Bacteroides. They also have reviewed the literature thoroughly and their paper is freely drawn on in this report of clinical observations. According to these authors, Veillon and Zuber<sup>5</sup> (1897) are generally credited with the most important early work. They

reported twenty-five cases of fetid and gangrenous suppuration and described various anaerobes as the etiologic agents. Veillon and Zuber said that their research was inspired by the paradoxical observations, previously made by Widal and Nobécourt,<sup>6</sup> that pus from gangrenous tissues contained many bacteria, as demonstrated by direct smear, but that on culture either very few organisms grew or the culture (aerobic) remained sterile. Veillon and Zuber then undertook a systematic research on gangrenous processes associated with fetid suppuration. Two articles, one by Teissier, Reilly, Rivalier and Layani,<sup>6</sup> and one by Teissier, Reilly, Rivalier and Stéfanesco,<sup>7</sup> contributed important clinical and bacteriologic data on infections caused by *Bacteroides funduliformis*. These authors gave an excellent review of the literature on anaerobic organisms. They reported four cases in which septicemia was caused by *Bacteroides funduliformis* and in which the diagnosis was made by culture of the blood for anaerobic organisms.

The literature on this subject has been less extensive in the United States than in other countries. Norris<sup>8</sup> described a case in which pyelphlebitis was associated with an anaerobic bacillus. Harris<sup>9</sup> reported a case of pyemia that was caused by a nonsporulating bacillus, which he named "Bacillus mortiferus." Oliver and Wherry<sup>10</sup> described a gram-negative nonsporulating anaerobic bacillus that utilized hemoglobin for the production of an extracellular melanin or melanin-like substance, which they named "Bacterium melaninogenicum." They isolated this organism from the pharynx, tonsils, infected surgical wounds, urine and feces. Burdon<sup>11</sup> found *Bacterium melaninogenicum* in the mouths of normal human beings and of animals as well as in cases of pulmonary abscess and pyorrhea. He also found this organism in the uterus and blood stream in cases of puerperal fever. He believed that the presence of the organism was an index of pollution and that it played an important part in various pathologic processes, although it was not pathogenic for laboratory animals.

Thompson and Beaver<sup>3</sup> reported two cases of sepsis associated with the formation of abscesses in the lungs; in both cases they thought that the condition had been caused by *Bacteroides funduliformis*. Cohen<sup>12</sup> reviewed the literature and reported the results of original research on the bacteriology of abscess of the lung; he called attention to the disregard in previous reports for anaerobic flora in abscesses of the lung. Among other organisms, he encountered *Bacteroides funduliformis*. Beaver, Henthorne and Macy<sup>13</sup> reported two cases of sepsis associated with hepatic abscess, caused by *Bacteroides funduliformis*. Henthorne, Thompson and Beaver said "It is clear then that strict anaerobes which

5. Quoted by Henthorne, Thompson and Beaver.<sup>4</sup>

The method of blood culture employed deserves mention. Four cc. of blood was drawn under sterile conditions from the antecubital veins of the patient. This was distributed in amounts of 1 cc. to each of two bottles containing approximately 40 cc. of beef infusion broth adjusted to a  $p_{H}$  of 7.6 to 7.8, the remaining 2 cc. being used to make two agar pour-plates, 1 cc. of blood being used for each. The broths and plates were incubated at 37 C. and read at intervals of twenty-four hours for five days. In cases in which positive cultures were obtained, the plates and the broths invariably showed growth within forty-eight hours. It seems necessary to outline our technic in view of recently reported methods<sup>7</sup> by which an unusually high percentage of positive blood cultures has been obtained in both normal and pathologic conditions. It must be remembered that these methods make use of large

count on the fifth day showing 50,500 white cells with 85 per cent polymorphonuclears, of which 54 were immature forms. A culture taken on the fourteenth day revealed approximately 80 colonies of hemolytic streptococcus per cubic centimeter of blood. On the fifteenth day the blood stream invasion increased to 500 colonies. Shortly before her death on the sixteenth day of illness, blood culture showed 400 colonies. The patient had received serum therapy and showed type-specific agglutinins in the blood appearing on the sixth day and persisting until the twelfth day. On the fourteenth day, when streptococci were recovered from the blood, type-specific agglutinins for pneumococci had disappeared and remained absent until the time of her death. Permission for necropsy was refused.

This case appeared to be progressing favorably under serum therapy and showed immunologic evidence of recovery from the pneumococcal infection until late in the disease (fourteenth day), when streptococcal septicemia developed. That the virulence of the organism was great is attested by the relatively rapid onset and short fulminant course leading to death from this complication.

CASE 2.—P. M., a white man, aged 39, admitted on the fifth day of the disease, showed type II pneumococcal pneumonia with massive consolidation of the right lower lobe and right middle lobe. The temperature fell by lysis, reaching normal on the tenth day, following which he had a low grade intermittent fever during the next two weeks. This was followed by a period of normal temperature for nearly two weeks except for a rise to 102 on two successive days. Following this, on the thirty-ninth day, his temperature rose and remained elevated with wide and inconstant fluctuations from 99 to 105 F. until the day of his death on the fifty-fifth day of illness. Agglutinins for the infecting type of pneumococcus developed on the tenth day of illness, which persisted until death. Repeated blood cultures during his early stay in the hospital were sterile.

On the nineteenth day of his disease a thoracentesis revealed the presence of thick, yellowish green pus, which on culture showed type II pneumococci. Two days later a thoracotomy was performed, and a large amount of thick pus was evacuated and the pleural cavity drained and packed. This was followed by apparently adequate drainage for two weeks during which time the temperature remained normal. Subsequently his temperature began to rise, and for this reason a further exploration of the thoracotomy was performed on the forty-second day. This revealed only a few cubic centimeters of pus, nor did the physical changes adequately explain the prolonged fever. On the fifty-fourth day of his illness he began to show symptoms of cerebral irritation, and three days later the clinical picture was that of a meningitis. A spinal tap at this time showed a purulent fluid from which *Streptococcus haemolyticus* was cultured. Unfortunately, during this last bout of fever no blood cultures were taken until the fifty-eighth day, when the broth showed *Streptococcus haemolyticus*, the plates showing no growth. A white cell count showed 29,800 cells with 58 per cent immature polymorphonuclears, the highest ever noted in this case. A blood culture taken a few minutes following death on the fifty-ninth day revealed no growth on the blood agar plates but the presence as before of *Streptococcus haemolyticus* in the broth, pointing to a minimal blood stream invasion. It is of interest to note that the urine showed albumin, casts, red cells and white cells, and *Streptococcus haemolyticus* on culture. At necropsy, an abscess cavity was found at the base of the right lung, being about 4 cm. in diameter, resting on the diaphragm and having a grayish white friable necrotic wall. There was no fluid present in the pleural cavity. There was no evidence of endocarditis or pericarditis. The brain showed a purulent leptomeningitis and the presence of two abscesses in the cortex of the frontal lobe. The kidneys showed numerous subcapsular petechiae, giving the organ the "flea-bitten" appearance of an embolic glomerulonephritis. Cultures from the brain abscess, the spinal fluid and the lung abscess revealed *Streptococcus haemolyticus*.

This case is one of a type II lobar pneumonia in which a type II pneumococcal empyema developed which was improved by surgical drainage. This

Temperature and results of blood culture in case 1.

quantities of the patient's blood (as much as from 20 to 30 cc.) as well as specially prepared mediums together with frequent subcultures. These highly refined methods contrast sharply with the technic just outlined for routine blood cultures.

#### REPORT OF CASES

CASE 1.—M. R., a Puerto Rican woman, aged 58, admitted on the fifth day of the disease, showed type I pneumococcal lobar pneumonia of the left lower lobe. Because of physical signs suggestive of fluid, a thoracentesis was done on the eighth day of illness and 10 cc. of a cloudy brown fluid showing 90 per cent polymorphonuclear leukocytes on the differential smear was obtained; this fluid when cultured on blood agar and blood broth was sterile. She received type I serum intramuscularly and progressed favorably, the crisis occurring on the tenth day, as shown in the accompanying chart. Following a period of defervescence lasting for four days, her temperature rose to 103 F. on the fourteenth day, remaining at that level until her death on the sixteenth day. Repeated blood cultures taken prior to the crisis were sterile. A white blood count on the thirteenth day showed 30,200 cells with 87 per cent polymorphonuclears, of which 67 per cent were immature forms, a relative "shift to the left" of the Schilling index when compared to a

7. Cecil, R. L.; Nicholls, E. E., and Stainsby, W. J.: Bacteriology of the Blood and Joints in Chronic Infectious Arthritis, *ibid.*, 26:6 (Oct.) 1928. Grant, E. T.: Blood Cultures in Chronic Arthritis, *J. Infect. Dis.* 52: 230 (March-April) 1933.

It appeared to be fixed posteriorly and considerable infiltration was present. A specimen for biopsy was found to be adenocarcinoma, grade 2.

May 31, exploratory operation was performed through a left inguinal incision. The liver appeared to be normal and the growth was situated below the peritoneal fold. A permanent colonic stoma was made; posterior resection of the growth was to be performed later. Hiccupping occurred soon after operation and the temperature became elevated to about 101 F. in the afternoon. On the seventh postoperative day the temperature rose to 103 F. and then fluctuated from 97 to 103 F. each day, the pulse rate varying from 80 to 100 beats per minute. On the eighteenth day the patient complained of pain in the right lower quadrant of the abdomen. The lower loop of colon was irrigated on the twentieth day and, following this procedure, a violent chill and profuse perspiration occurred. Stridor was noticed on inspiration, but examination of the vocal cords did not reveal any abnormality. From the twentieth day on the temperature varied from 97 to 106 F. and the pulse rate from 80 to 170 beats per minute. Chills, accompanied by profuse sweating, occurred daily. On the twenty-first day the patient said that he felt fine. Three days later he became irritable, and death occurred on the twenty-fifth postoperative day.

At necropsy, multiple abscesses were found in the liver and lungs. The right pleural cavity contained 100 cc. of fluid and scattered adhesions. Two small, septic infarcts were found in the lung. The liver weighed 2,500 Gm. (normal weight, 1,500 Gm.). On the right margin of the right lobe of the liver was an elevated fluctuating nodule, 6 cm. in diameter, which was filled with thick, creamy pus. Another multilocular abscess, 7 cm. in diameter, was found in the same lobe. Thrombosis of the portal vein was not present. Localized abscesses were found in the depths of the malignant tumor and in the adjacent wall of the rectum and perirectal tissue. Peritonitis was not present.

CASE 3.—A woman, aged 37, came to the clinic Oct. 12, 1933, because of rectal pain, blood and mucous in the stools, and diarrhea of from two to ten bowel movements a day for one year; she had had a fever of low grade for six months.

On proctoscopic examination a large movable carcinoma was found, which involved the anterior half of the lower third of the rectum. It did not obstruct the lumen of the bowel. A specimen for biopsy was reported to be adenocarcinoma, grade 2. October 16, colostomy was performed in the left inguinal region under spinal anesthesia. Metastasis had not occurred in the liver. The growth could be palpated at the peritoneal fold. Posterior resection was to be performed later.

Convalescence was uneventful until the eighth postoperative day, when the temperature was elevated to 102.6 F.; from this time until the patient died the temperature ranged from 97.8 to 105.8 F. each day, and the pulse rate from 90 to 160 beats per minute. Perspiration was profuse. Bilateral bronchopneumonia developed on the fifteenth day. A blood culture was taken on the twelfth day and, six days later, *Bacteroides funduliformis* was reported to be present. Jaundice appeared on the fourteenth postoperative day and became more severe. The patient died on the twenty-first postoperative day.

At necropsy, multiple abscesses in the liver and lungs, and beginning empyema were found. The spleen was about four times the normal size. Numerous raised yellow nodules, from 1 to 2 cm. in diameter, with sharply demarcated borders, were present over the surface of the lungs. These nodules contained a greenish yellow pus. Similar nodules were found throughout the lung. The liver contained five abscesses, which averaged 2 cm. in diameter. These abscesses were filled with yellow fluid. One abscess was multilocular and measured about 4.5 cm. in diameter. A purulent thrombus was found in a branch of the portal and right and left sublobular veins. A faintly putrid, greenish pus exuded from the veins when they were cut. A raised mass, about 5 by 4 cm., was found on the mucosa of the rectum, and an ulcer was present at the border of the mass. This ulcer contained tiny sinuses, from which pus exuded. A pool of pus was found between the malignant mass and the rectal wall. Peritonitis was not present.

CASE 4.—A woman, aged 51, was admitted directly to the hospital Jan. 20, 1934, as an emergency case because of partial intestinal obstruction which had been present for six days.

For two years she had had periodic attacks of abdominal cramps, and for one year constipation had increased in severity and blood occasionally had been found in the stools. Chills and fever had not occurred.

The patient was obese; she weighed 176 pounds (80 Kg.). Moderate abdominal distention and considerable borborygmus were present. Proctoscopic examination revealed a movable annular carcinoma situated 24 cm. above the anus. A specimen taken for biopsy was found to be adenocarcinoma of grade 1.

January 23, vaccine was injected intraperitoneally. Three days later, under spinal anesthesia, a rather difficult type of resection was performed for obstruction. Metastasis was not found in the liver and glandular involvement could not be demonstrated. The three-bladed clamp on the colon came off on the eighth postoperative day. On the twenty-eighth day an injection of vaccine was again administered intraperitoneally and three days later the colonic stoma was closed. The immediate convalescence was somewhat stormy; the temperature became elevated steadily to 104.4 F. and the pulse rate increased to 120 beats per minute on the fourth day after the colonic stoma was closed. At this time a radium pack was applied for parotitis on the right side. A small amount of purulent material drained from the wound during the remaining convalescent period. The temperature and pulse returned to normal in a few days. A culture from the wound taken February 20

Fig. 2.—Section of rectal carcinoma that has become infected with *Bacteroides funduliformis*, with resultant formation of abscess. Slightly reduced from a photomicrograph with a magnification of 28 diameters.

revealed the presence of *Bacteroides funduliformis*. A small amount of purulent material drained from the wound on the twenty-third postoperative day and continued to drain for a short time. The patient was dismissed on the twenty-ninth day after closure of the colonic stoma.

CASE 5.—A man, aged 35, came to the clinic Oct. 22, 1935, because of constipation, loss of weight and bloody stools, which had been present for one year. Considerable mucus had been passed for three months and the stools had been streaked with blood for the past six weeks. He had lost 40 pounds (18 Kg.) during the previous year. Chills, fever or jaundice had not occurred. One massive hemorrhage had occurred three weeks previously. Hemorrhoidectomy had been performed one month before he came to the clinic.

On physical examination the patient appeared to be well developed and fairly well nourished. He weighed 179 pounds (81 Kg.). The blood pressure in millimeters of mercury was 132 systolic and 84 diastolic, the pulse rate 82 beats per minute and the temperature, normal. The value for hemoglobin was 15.4 Gm. per hundred cubic centimeters of blood; erythrocytes numbered 4,450,000 and leukocytes 5,900 per cubic millimeter. Proctoscopic examination revealed a movable, annular carcinoma, beginning 12 cm. above the anus, which partially obstructed the lumen of the rectum. A specimen taken for biopsy was found to be adenocarcinoma, grade 2.

October 30, 1 cc. (one billion organisms) of peritonitis vaccine was injected intraperitoneally. The temperature rose to 101.4 F. in a few hours and returned to 98 F. the following

lobe. He had a persistently elevated temperature ranging from 104 to 105 F. till his death on the tenth day of illness. Clinically he showed evidence of marked toxemia. On admission, blood culture showed a minimal invasion with type I pneumococcus (8 colonies per cubic centimeter). Following serum therapy the blood was sterile for the next four days until the eighth day of his illness, when the broth culture showed a growth of type I pneumococcus in the blood, the plates being sterile. Following further serum administration, a culture on the ninth day was sterile. On the day of his death the blood culture again became positive, showing three colonies of pneumococcus type I and 15 colonies of *Streptococcus haemolyticus* per cubic centimeter of blood. The white blood count on admission was 18,900 with 96 per cent polymorphonuclears, of

probably being due to the streptococcus, since cases of fatal pneumococcic bacteremia show higher bacterial counts as a rule.

CASE 7.—J. B., a white man, aged 50, complained of a cough productive only of mucus for six weeks before admission. A week later he began to have pain in the right ankle, right shoulder and right knee, which subsided. On admission he complained of pain in the chest as well as in the left ankle and left knee. Physical examination showed consolidation of the right lower lobe and acute arthritis of the left knee and ankle. The sputum at first was thick, mucoid and rusty, and sputum typing revealed a group IV pneumococcus (unclassified types I to VIII). Similarly, a blood culture taken the day after admis-

which 58 per cent were immature forms. Serial blood counts showed a slight fall in the total white cells, although there was some tendency to increase of the immature forms. On the eighth day the count was 14,200 white cells with 94 per cent polymorphonuclears, of which 60 per cent were immature forms, while on the tenth day, when streptococci were first found in the blood, the count was 35,900 cells with 88 per cent polymorphonuclears, of which 67 per cent were immature forms. Specific antipneumococcus agglutinins did not appear until the day of death, and then only in minimal dilution. Necropsy showed consolidation of the right upper lobe, in the stage of gray hepatization. No other noteworthy changes were present.

This case is of definite interest because of the presence of dual invasion of the blood stream. It might be argued that the serum therapy held the pneumococcic bacteremia under partial control, fatal termination

sion showed an unclassified pneumococcus in the broth. Seven days after admission he had a severe coughing spell with a hemoptysis of 4 ounces (120 cc.) followed by the expectoration of a large quantity of purulent hemorrhagic sputum, and the sputum retained this character until his death. Repeated search revealed no tubercle bacilli.

Seven days after admission, there appeared a few petechiae in the mucous membrane of the mouth, which disappeared in a few days. There was no evidence of endocarditis and no hematuria or other signs of embolic phenomena. At approximately the same time, an abscess of the left hand developed which was incised, evacuating about a half ounce (15 cc.) of thick yellow pus, which on culture showed *Streptococcus haemolyticus*. A blood culture taken on this day also showed *Streptococcus haemolyticus*, there being 10 colonies per cubic centimeter of blood. The blood culture was not repeated until twelve days later, when it was sterile. The case ran a typical course, abscesses developing in the right forearm, left sternum,

liver was affected and the degree of jaundice varied from moderate to extreme. This jaundice probably was not entirely of hepatic origin but might be similar in origin to that found in cases of severe streptococcic infection. In some cases the jaundice was present before other signs of a grave complication were in evidence. The jaundice occurred from four to seven days after the onset of the postoperative infection and usually progressed to an extreme degree. In two cases jaundice was not present, and one of these patients recovered.

The usual indication of a break in the uneventful convalescence was a chill and a sudden elevation of temperature. Profuse exhausting sweats occurred. Usually one chill occurred each day, but in some cases two chills occurred and in other cases there were chills every other day. The temperature was of the usual septic type, ranging from 97 to 106 F.

An apparently distinctive feature of postoperative *Bacteroides* septicemia was the profuse perspiration. Many changes of linen were required each day. The sweating that occurs in streptococcic septicemia is not nearly so severe as that which occurred in these cases. Exhausting chills and sweating were present in every case except the one in which recovery occurred and in which bacteremia was not present.

The increase in pulse rate usually was in proportion to the elevation of temperature. In almost every case the quality of the pulse was good until a few days before death. This feature was noticed independently by several consultants. The pulse rate ranged from 80 to 160 beats per minute. General malaise and exhaustion were extreme in all cases in which death occurred. In the five cases that ended fatally, death occurred from fifteen to twenty-one days after the onset of septicemia.

The presence of mild symptoms in the one case in which recovery occurred might indicate that infection by *Bacteroides funduliformis* is more prevalent than it usually is considered to be and that it might be present in cases in which short, postoperative febrile attacks are encountered. In the case in which recovery occurred, the maximal temperature was noted on the fourth postoperative day, the temperature returning to normal in a few days. The presence of *Bacteroides funduliformis* in the culture from the wound in this case again indicates the importance of considering this organism as a causative factor in postoperative complications. In several of these cases, manipulations of various types were performed from two to three days prior to the onset of symptoms. This indicates the ever present danger of septicemia from wound infections and emphasizes the need of care, especially in cases in which operation has been performed on the large bowel, which is notoriously heavily infected.

Blood cultures may not become positive for from five to seven days after the onset of symptoms and they should not be discarded if no growth occurs in forty-eight hours. When *Bacteroides* septicemia is suspected, repeated blood cultures should be taken.

#### TREATMENT

Specific treatment is not available, the usual supportive measures being used. A positive water balance was obtained by intravenous administration of dextrose in physiologic solution of sodium chloride. Most of the patients were able to take fluids by mouth until they became confused by the severe toxemia. Intravenous administration of 1 per cent solution of gentian violet

was employed in those cases in which an infection of the blood stream was evident early. An oxygen tent was used when dyspnea or cyanosis was present. Pruritus that accompanied the jaundice was not of sufficient intensity to require treatment. A solution of dextrose was administered intravenously when evidence of hepatic damage appeared.

#### SUMMARY AND CONCLUSIONS

In six cases of *Bacteroides funduliformis* infection the infection occurred after operations for carcinoma of the colon. Only one of the six patients recovered, the mortality therefore being 83 per cent. At necropsy, multiple abscesses were found in the liver in every case in which death occurred. Blood culture for *Bacteroides funduliformis* should be made in cases in which icterus occurs after operation, even though other signs of septicemia may not be present. Early cultures from wound and blood for anaerobic bacteria are necessary in order to make a diagnosis before death. Specific treatment is not available.

#### SURGICAL PRONE POSTURE

ALBERT H. MILLER, M.D.

PROVIDENCE, R. I.

Besides such well recognized causes of preventable surgical deaths as broken asepsis, insecure ligatures and incompetent anesthesia, the influence of ill advised posture must also be considered. Not only is a posture that would be trying to a conscious subject equally injurious to an anesthetized patient, but its harmful effect is intensified by the tissue relaxation that is an essential part of the action of the anesthetic.

Fig. 1.—Operation of the synchronous pneumograph: The applicators encircle the chest at the ensiform level and at the abdomen about 4 inches lower. Each applicator consists of two measuring tapes, one rigid, the other extensible. They constantly measure changes in the circumference of an object to which they are applied. Each applicator is connected by a silk cord moving freely within a flexible tube, to one of the pens of a polygraph.

The dorsal recumbent posture with the head slightly lowered, advantage being taken of the effect of gravity to aid the venous return to the heart and to maintain the cerebral blood pressure, is the most favorable for the anesthetized patient. Friedrich Trendelenburg early found that his high pelvic posture was not free from the danger of circulatory embarrassment and advised against its use for fat patients. The Fowler postoperative posture, draining away the blood from cerebral centers, has contributed to many fatalities. On the change from the dorsal to the sitting posture, anesthe-

ation of *Streptococcus viridans* with endocarditis, it is also interesting to note that at no time was there any clinical evidence suggestive of valvular disease or embolic phenomena.

## COMMENT

In considering the streptococcus as a secondary invader in pneumococcic lobar pneumonia, it must be borne in mind that this organism may manifest itself either by a local pulmonary complication or a systemic blood stream invasion. Clendening's<sup>8</sup> review of the local pulmonary complications, in which he divides these lesions into (a) cases of empyema, (b) localized areas of pulmonary infection, (c) lung abscess and (d) delayed resolution, provides a convenient classification. A critical study of his cases and of those of other authors shows a singular lack of reported evidence of blood stream invasion. This would tend to point to a high degree of elective localization that the streptococcus enjoys when it complicates pneumococcic pneumonia. It is our impression, however, that streptococcic bacteremia is more common than the literature would indicate. Its infrequent recognition may be in part accounted for by the sparsity of routine attempts at blood culture during the occurrence of these complications. This is attested by our own observations, in which patients showing local involvement have been found on frequent cultures to show evidence of invasion of the blood.

Up to the present time we have been able to find only seven authentic cases comparable with the foregoing reported group, the salient features of which are summarized together with those of our own cases in the accompanying table. These include the three cases observed by Parsons and Myers,<sup>1</sup> the case of Johnston and Morgan,<sup>2</sup> the two cases of Cole,<sup>2</sup> and the case mentioned by Lyon.<sup>4</sup> Among the earliest reports is that of Netter,<sup>9</sup> who mentions two cases, one of suppurative streptococcic meningitis following a postpneumonic lung abscess, and one of multiple arthritis following a pneumonia. In these two cases the path of spread from the lung is in doubt as no mention is made of blood cultures, but it would seem likely that the distal lesions resulted from blood stream invasion. In the recent article by Finland,<sup>10</sup> dealing with mixed infections in pneumococcic pneumonia, he mentions a patient with type VIII infection who during life showed sterile blood cultures and the presence of agglutinins for the infecting type, who nevertheless died, showing at necropsy a pure culture of *Streptococcus haemolyticus* in the heart's blood. There is one uniform feature about these cases, as the table will demonstrate; namely, that the bacteremia occurred relatively late in the disease, the earliest occurring on the seventeenth day, the latest on the fifty-fourth day. Our own observations are in the main in agreement with these observers on this point. In addition, they illustrate other interesting features, the most noteworthy being the possibility of recovery from this complication. Thus, it is seen that two of our patients showing transient minimal blood stream invasions recovered.

An analysis of our group of eight cases elicits certain facts, as shown in the table. There were seven

men and one woman. This preponderance of males may be attributed in part to the greater number of male patients observed during this period, the ratio being 2 to 1. The age of the patients varied from 28 to 58, the majority of the cases occurring in the fifth and sixth decades. This is in contrast to the frequency of uncomplicated cases of pneumonia occurring in the younger age groups. Apart from age, it is of interest to speculate as to the possible presence of certain predisposing factors which may theoretically account for lowered "resistance." That alcoholism may play a rôle is evidence by the fact that in six of our eight cases there was a previous history of chronic alcoholism, an incidence admittedly higher than that usually noted in the medical wards of Bellevue Hospital.

In the face of the previous reports it must be granted that our group shows an abnormally high incidence of this rare complication. Thus, during the season 1933-1934, when approximately 100 cases were observed, this condition occurred in five cases; during the season 1930-1931, with approximately the same number of cases, it occurred twice, and in 1932-1933 it occurred once.

In connection with the association between streptococcic septicemia and the infecting type of pneumococcus, it would seem to be more than chance that four of the eight cases were of type I pneumococcus. The date of the onset of the bacteremia as far as we were able to tell occurred on the fourteenth, fifty-eighth, twelfth, twenty-eighth, twenty-eighth, tenth and fifth days in cases 1, 2, 3, 4, 5, 6 and 8, respectively. In case 7 the day of disease was unknown. It will be seen that the majority occurred relatively late in the disease, usually after the second week, when the patient gave clinical and immunologic evidence of recovery from his pneumococcic infection, at a time when the normal expectation was that of uneventful recovery. It is noteworthy that in seven of our cases agglutinins for the infecting pneumococcus developed during the period of observation, which is additional evidence that the original infection was due to this organism.

In considering a relationship between the blood stream invasion and the persistence of local disease, it is evident from our study that six of the eight cases presented local pulmonary involvement such as empyema or delayed resolution at the time at which blood stream invasion occurred. Apart from cases 2, 3 and 7, in which *Streptococcus haemolyticus* was recovered from the local lesion, unfortunately we have no bacteriologic data that established any etiologic relationship between the pulmonary lesion and the blood stream invasion. The invading organism in seven of the cases was *Streptococcus haemolyticus* (beta) and in one case *Streptococcus viridans* (alpha). Six of the seven patients with *Streptococcus haemolyticus* bacteremia died; one recovered. The patient with *Streptococcus viridans* bacteremia recovered.

It is dubious whether an analysis based on the previously reported cases and those of our own provides one with a clear enough symptom complex to warrant a diagnosis of this rare complication. It would seem instead that the diagnosis must be arrived at largely by a process of exclusion in which careful physical examination, x-ray evidence and thoracentesis are used to rule out empyema or recrudescence of the pneumonia. In this connection a sudden increase in the leukocytes with a marked rise in the percentage of immature granulocytes, a so-called shift to the left of the Schilling

difficulty take up the work of respiratory movement. The synchronous pneumographic tracing shows diaphragmatic excursions rapidly diminishing in extent until they entirely disappear with thoracic movements of lessened amplitude but increased frequency; a picture of labored, insufficient respiratory action, which may aid in explanation of the state of prostration that has often accompanied protracted employment of the prone posture.

To diminish the respiratory handicap that has been generally recognized as associated with use of the prone posture, it has been customary to lift one shoulder on a pillow with the object of freeing thoracic movement from part of its encumbrance. It must be acknowledged that this procedure has not been very successful. The patients have still presented indications of dyspnea for a reason that is now clear. The thoracic respiratory movements are paralyzed by the effect of the anesthetic, and efforts to restore them by modification of posture are of slight benefit. Instead, the diaphragmatic respiration must be restored. This can be done by raising the pelvis on a small pillow placed transversely underneath the anterior superior spines. Improvement in respiration is immediately noticeable.

Fig. 7.—Twenty-five minutes omitted between figures 6 and 7. Abdominal respiration has been perfectly maintained throughout the operation in the prone posture with the pelvis supported on a small pillow. The anesthetic is now discontinued and recovery is indicated by some irregularity in respiratory movement. In spite of partial recovery from the anesthetic effect, the abdominal respiratory movements are markedly restricted when the pillow is removed.

The synchronous pneumograph shows diaphragmatic movement proceeding normally, and thoracic movements also improved. This simple procedure is worthy of trial whenever the prone posture is to be used.

#### CONCLUSIONS

When the thoracic respiration has been paralyzed by the action of an anesthetic, effort should be concentrated on freedom of diaphragmatic movement.

In the prone posture, freedom of diaphragmatic movement is favored by slightly elevating the pelvis on a pillow placed transversely under the anterior superior iliac spines.

**New Tuberculin Aids Cattle Health Campaign.**—A new tuberculin, free from foreign protein and superior to the tuberculin formerly available, has been in use since last April in the testing of cattle for tuberculosis, the U. S. Department of Agriculture reports. Enough new tuberculin is being produced to test more than 18,000,000 cattle annually. The new tuberculin is even more reliable in revealing the presence of tuberculosis than the broth tuberculin which for more than forty years has been produced by practically the same method as was devised by Robert Koch, discoverer of the product. The new tuberculin is prepared from cultures on a synthetic medium composed of pure chemicals. The most important single ingredient in this medium is asparagine, a pure crystalline amino acid, which furnishes the nitrogen the bacteria require without introducing any protein whatever.

## STREPTOCOCCIC SEPTICEMIA COMPLICATING PNEUMOCOCCIC LOBAR PNEUMONIA

SAUL SOLOMON, M.D.

AND

THEODORE J. CURPHEY, M.D.

NEW YORK

With the more general application of bacteriologic study in pneumonia, the presence of the streptococcus as a secondary invader is becoming increasingly recognized as of major importance. This is especially evident in cases in which there have been local pulmonary complications following the initial infection by the pneumococcus.

There is another group of cases, however, in which bacteriologic investigation has been of even greater value in elucidating the clinical picture; namely, those showing systemic blood invasion by the streptococcus in the course of pneumococcic pneumonia. Judging from the reports in the literature, the number of recorded cases in which this occurs is apparently few. A recent report by Parsons and Myers<sup>1</sup> presents three cases. Cole<sup>2</sup> reports two cases. Johnston and Morgan<sup>3</sup> and Lyon<sup>4</sup> each report a single case.

Our purpose in this report is to add eight cases to those already described. We do not propose here to discuss local (pulmonary) streptococcic infections following pneumococcic lobar pneumonia but rather to limit ourselves to an attempt to determine whether there exists a characteristic clinical entity, the result of blood stream invasion by the streptococcus occurring usually late in the disease and for that reason, perhaps, not having received sufficient clinical emphasis up to the present time. In a recent article on the cause of death in pneumonia, Harlow Brooks<sup>5</sup> stresses the fact that sepsis is the most significant factor. We concur in this opinion and wish to add that not only the pneumococcus but also the streptococcus must be borne in mind as the invader of the blood stream.

#### METHOD OF STUDY

The cases summarized here were admitted to the Fourth Medical Division of Bellevue Hospital during the seasons of 1930-1931 and 1932-1934, in the services of Dr. Charles Nammack, Dr. Harlow Brooks, Dr. Anne Von Sholly and Dr. Harry Solomon. These cases form part of a group observed in the course of a study as to the therapeutic value of certain antipneumococcic "exudate" serums.<sup>6</sup> Each case admitted to this group had sputum typings which were repeated when necessary; frequent and, when indicated, daily blood cultures as well as blood counts and agglutination tests were taken. The patients were observed clinically from day to day and, when necessary, were examined roentgenologically.

milk, cheese and a host of other routine test materials of no importance in this discussion. Mold extracts were not available for testing at that time.

*Course.*—The patient was under our care from 1932 to 1935. For short periods out of pollen season she was fairly comfortable. Frequent colds, however, seemed to precipitate asthmatic seizures, and with many of these she raised bloody sputum. She was found to be iodine sensitive, and the use of iodides in any form had to be discontinued. Other supplementary therapeutic aids were of little real value, and a trial of non-specific desensitization with a defatted milk preparation was begun. On this management she seemed to improve. The initial use of 0.02 cc. intradermally was gradually increased every three or four days. She eventually received after about sixteen weeks a dose of from 0.7 to 0.8 cc. weekly. It was at this time that the appearance of slight local reactions at the site of inoculation (part intracutaneously and part subcutaneously) caused the dose to be reduced, first to 0.6 cc. and then to 0.4 cc. On the twenty-seventh injection, nineteen weeks after onset of milk therapy, a dose of 0.4 cc. produced severe asthma and unmistakable shock. Epinephrine was required to restore the patient to her former comfortable state. A large local reaction appeared at the site of the milk injection. The plunger of the syringe had been withdrawn previous to delivery of its contents to guard against intravenous injection.

One month later we were able to resume therapy with 0.02 cc. dosage. This caused local redness 2 cm. in diameter. Six months later she was started on mixed vaccine, but little improvement was noted until a nonspecific mammalian serum was used. This seemed to give some relief, but fear of the approaching pollen season caused her to return to Germany and no reports of her have been obtained since.

The reaction to milk is just one of the many interesting phases of this patient's course and management. Similar reactions to parenteral injection of milk derivatives have appeared in the literature<sup>1</sup> but they have apparently been relatively infrequent. There are at least two rather popular milk preparations now being used in nonspecific protein therapy, and an investigation of their sensitizing properties now seemed in order. We report them briefly.

#### SENSITIZING PROPERTIES OF MILK PREPARATIONS

Guinea-pigs were injected subcutaneously and intravenously with 0.8 cc. of a fat-free digested milk which we shall call product A. This was repeated twice within ten days. Three weeks later intradermal tests on these animals were distinctly positive to product A, and 0.8 cc. intravenously produced prompt fatal anaphylaxis. The serums of two rabbits similarly made sensitive were studied for precipitins, but the presence of an interfering substance in the antigen (presumably the benzyl alcohol preservative) made the readings unreliable and therefore inconclusive. In the rabbits intradermal tests to this product were negative, and we did not succeed in producing anaphylactic shock.

Similar investigation of two other specimens of product A yielded entirely negative results. Chemical analysis showed product A used in the first experiment to contain 0.5 Gm. of protein per hundred cubic centimeters and in the second experiments, in which sensitization failed, 0.24 Gm. Whether the failure to sensitize was due to the decreased protein content of the second specimen of product A or to a change in animal sensitivity can only be surmised. Of practical importance is the fact that sensitivity was definitely established.

Finally, one other preparation (to be called product B) was studied. This product, the other of the popularly used milk materials, is described as "defatted, sterile milk." It produced sensitization, and typical fatal anaphylaxis without exception. Chemical analysis showed product B to contain 3.06 Gm. of protein per hundred cubic centimeters.

#### COMMENT

Such clinical and experimental data leave little doubt that potentially dangerous sensitizations can be established by the use of proteins in nonspecific parenteral therapy. The dangers of this therapy if this type of management seems indicated<sup>2</sup> can be greatly minimized by the very careful scrutiny of the patients under such management, especially following injections of these materials. The question of choice of material is also important. If the protein used is related closely to dietary or environmental proteins one would do well to substitute for it a substance, if not completely unrelated, at least remote enough so as to constitute no real hazard of cross-sensitization (e.g., typhoid vaccine, biologically remote serums). The feeling among allergists that the presence of one sensitivity makes subsequent sensitizations more likely, and the experimental proof of this in the work of Hektoen and others, would suggest the advisability of reducing the use of nonspecific foreign protein therapy of all types to a practical minimum.

### Clinical Notes, Suggestions and New Instruments

#### PHLEGMON OF THE PTERYGOPALATINE FOSSA FOLLOWING INJURY TO HARD PALATE WITH LOLLIPOP STICK

WILLIAM A. SCHONFELD, M.D., NEW YORK

On review of the literature I was unable to find any report of an injury within the mouth caused by a lollipop stick. I was likewise unable to find any report of death resulting from such an injury on inquiry from the United States Bureau of Census, the New York State Bureau of Vital Statistics and the medical examiner of New York City.<sup>1</sup> This does not imply that such cases do not exist but rather that the accidents were not listed as causes of death. There are, however, deaths recorded as the result of an injury within the mouth by other seemingly innocuous articles.<sup>2</sup> Undoubtedly there are many cases of injury within the mouth by sharp objects including lollipop sticks presenting serious subsequent complications in which the illness of the individual is not attributed to the injury, which seems insignificant. This is what occurred in the case to be described until late in the course of the illness.

Some candy manufacturers to facilitate production make lollipops with sharply pointed sticks, which are potentially lethal weapons; others use straight sticks, which are much less dangerous (fig. 1). Children frequently run about with lollipops in their mouths, and as often happens the child may fall on his face. The stick may thus be forced through the candy to penetrate the palate, pharynx, gums or cheeks. Many parents who would ordinarily forbid a child to run about with a pencil or other sharp object in his mouth do not hesitate to allow him to do this with a lollipop, not realizing the great danger involved. I believe that lollipops with sharply pointed sticks should be forbidden at all times. Those with blunt sticks may be given to a child, but he should be cautioned not to run about with one in his mouth.

The incidence of injuries within the mouth of children by lollipop sticks is relatively high, although none are reported in

The author is indebted to the Department of Pathology of Memorial City Hospital, Dr. William Aronson, director, for the detailed post mortem data.

1. Personal communications to the author.  
2. Bruggemann, Alfred: Mond- und Rachenverletzungen, in: Handbuch der gesamten Unfallheilkunde 4: 266, 1934.

followed by a prolonged convalescence, during which there developed clinical and bacteriologic evidence of *Streptococcus haemolyticus* meningitis, showing at the same time a minimal blood stream invasion by the same organism. It is worthy of note that the organism was recovered on postmortem culture from the lung abscess, the brain abscesses and the meninges. This offers two interesting features: first, the minimal invasion of the blood associated with extensive metastatic foci elsewhere; second, clear demonstration of the path of spread by way of the blood stream. In all probability, the primary source of the streptococcus was the lung abscess, whence the organism invaded the blood stream, establishing remote focal involvement in the kidneys and the brain. The relationship between cortical foci and leptomeningitis is of special interest, as it illustrates in a pyogenic meningitis what Rich<sup>7a</sup> has demonstrated to be the usual evolution in cases of tuberculous meningitis; namely, that the meningeal involvement is in all probability the result of direct extension from the cortical focus.

CASE 3.—L. B., a white man, aged 47, admitted on the sixth day of the disease, showed a type I pneumococcal pneumonia of the right upper lobe which rapidly involved the remaining lobes, resulting in a massive consolidation of the entire right lung that persisted till death. His fever showed a tendency to remit during the period from the eighth to the tenth day. Daily blood cultures from the day of admission to the eleventh day were sterile. On the evening of the eleventh day his temperature rose to 102 F., subsequently rising to 104 on the twelfth day. On this day the blood culture showed *Streptococcus haemolyticus*, there being about 30 colonies per cubic centimeter of blood. On the thirteenth day the blood culture was still positive, there being about 20 colonies per cubic centimeter. On admission the patient showed no agglutinins for the infecting type of pneumococcus, but following intensive serum therapy intramuscularly agglutinins appeared on the eighth day of illness and persisted till death on the thirteenth day. On admission, the white cells numbered 19,800 with 94 per cent polymorphonuclear neutrophils, of which 72 per cent were immature forms, and on the day of death the white count reached 100,800, with 94 per cent polymorphonuclears, of which 70 per cent were immature forms—a leukemoid picture. Autopsy was not obtained. Immediately after death, however, a lung puncture was done, and culture of the lung juice showed *Streptococcus haemolyticus*.

The course of events and the fatal outcome in this case are quite typical of the picture seen in streptococcal septicemia. Thus the patient, while showing some clinical evidence of improvement and the presence of type-specific pneumococcus antibodies, developed a sudden exacerbation of the clinical picture with no demonstrable change in the pulmonary signs and symptoms, the cause of which remained obscure till the positive blood culture was obtained. A noteworthy feature of this case is the leukemoid blood picture at the time of bacteremia.

CASE 4.—W. P., a white man, aged 28, admitted on the fifth day of disease, showed a type IV pneumococcal lobar pneumonia of the right lower lobe. Crisis occurred on the tenth day. The patient remained afebrile until the twenty-first day, when his temperature rose to 102 F. From the twenty-first to the twenty-eighth day he had an irregular intermittent fever reaching as high as 104.6, returning to normal by lysis on the twenty-ninth day. During this time no satisfactory clinical evidence was found for the pyrexia. Empyema was suspected, but a roentgenogram taken early in the course and subsequent fluoroscopic examination later failed to disclose any fluid.

The patient was given nonspecific serum therapy from the fifth to the seventh day, developing mild serum sickness on the

thirteenth day, the symptoms disappearing in a few days. On the twenty-seventh day of his illness he developed generalized joint pains of moderate severity. Prior to this time, repeated cultures of the blood had been sterile, but on the day following the onset of arthritis the blood showed a growth of *Streptococcus haemolyticus* in the broth cultures, the blood agar plates being sterile. The temperature on the following day fell to normal. A culture taken six days later was sterile. The patient made a complete recovery and was discharged. The serum agglutinins for the infecting pneumococcus appeared on the fourteenth day of his illness and persisted until his discharge. On admission a blood count showed 13,800 white cells with 88 per cent polymorphonuclears, of which 60 per cent were immature forms. On the twenty-sixth day the count was 20,200 with 93 per cent polymorphonuclears, of which 72 per cent were immature forms.

This case presents a transient minimal invasion of the blood stream by *Streptococcus haemolyticus* occurring late in convalescence and after agglutinins for the infecting pneumococcus had appeared in the blood. That the quantitative factor plays an important rôle in recovery seems probable in view of the fact that the invasion was less than that usually seen in the fatal cases. It is interesting, moreover, to speculate on the relationship of the bacteremia to the multiple arthritis, a fair assumption being that it was one of cause and effect.

CASE 5.—C. P., a white man, aged 48, admitted on the fifth day of the disease, showed a type I pneumococcal lobar pneumonia of the right lower lobe. Crisis occurred on the seventh day following serum therapy. The temperature remained normal till the thirteenth day, when he began to show an intermittent fever varying from 101 to 103 F. for twelve days, following which, on the twenty-sixth day of illness, it rose to 105, remaining in that vicinity till his death on the twenty-ninth day. The physical signs over the involved lung at this time were such as to suggest delayed resolution. Blood cultures during the acute febrile stage on admission were sterile. Cultures taken on the last two days of his life showed a rapidly mounting bacteremia, there being 100 colonies of *Streptococcus haemolyticus* on the day of his death. The white count on admission was 12,000 with 91 per cent polymorphonuclears of which 56 per cent were immature forms. Serial blood counts showed a steady fall in both the total and the immature white cells, so that on the twenty-fourth day the white cells numbered 11,900 with 85 per cent polymorphonuclears, of which 36 per cent were immature. On the twenty-eighth day, the date on which the positive blood culture was obtained, the count rose abruptly to 22,600 with 97 per cent polymorphonuclears, of which 57 per cent were immature. Specific agglutinins for type I pneumococcus appeared on the seventh day of the illness and persisted until death. It is interesting to note also that there were no agglutinins present in the patient's serum for the invading streptococcus at the time the blood culture was positive. Autopsy was not obtained.

This case, to all intents, appeared to be a typical type I pneumococcal pneumonia with a favorable prognosis. The patient responded well to serum therapy and had his crisis on the seventh day of illness, coincident with the development of specific agglutinins, the only untoward event being the delay in resolution of the involved lung. It is a debatable question whether the rise in temperature occurring a week after the crisis was due to a local secondary infection of the lung or to a blood stream invasion by the streptococcus, from an undetermined focus. This point cannot be settled because blood cultures were not repeated till one day before death, when, of course, a well marked streptococcal septicemia was detected.

CASE 6.—J. C., a white man, aged 45, admitted on the second day of the disease with a type I pneumococcal pneumonia, showed consolidation of the right upper lobe and right middle

7a. Rich, A. R., and McCordack, H. A.: The Pathogenesis of Tuberculous Meningitis, *Bull. Johns Hopkins Hosp.* 52: 5 (Jan.) 1933.

A blood culture taken at this time showed 75 colonies of *Staphylococcus aureus* per cubic centimeter of blood. The spinal fluid still contained no organisms on smear and culture. The child became progressively worse and died the next day, three days after admission, with a temperature of 108 F. This was six days after the onset of symptoms, or fourteen days in all after the accident.

**Necropsy.**—The body was well developed and well nourished, with very pale skin. The left lower and upper lids were markedly swollen and hyperemic, with chemosis of the bulbar conjunctiva. The swelling extended laterally to the temporal region. The left temporal muscle was markedly edematous. At the posterior aspect of the hard palate about 2 cm. in front of the pterygoid process near the alveolar margin there was a small ulcer about 3 mm. in diameter. The surrounding palatal tissue was somewhat swollen and soft. There was a small collection of thick yellow-gray pus in the left lateral fissure between the temporal and the frontal lobes of the brain and also on the pia at the floor of the left frontal lobe. Sections through the brain revealed no gross abnormalities, but microscopically the meninges and the adjacent brain tissue were noted to contain large collections of polymorphonuclear leukocytes, lymphocytes, plasma cells, fibrin and areas of hemorrhages. The left

gopalatine fossa, the orbit and the abscesses of the kidney all revealed *Staphylococcus aureus*. The blood culture contained the same organism.

**Anatomic Diagnosis.**—1. Phlegmon of the pterygopalatine fossa secondary to trauma and infection of the palate. 2. Orbital cellulitis. 3. Endophlebitis of the cavernous sinus and ophthalmic vein on the left side. 4. Encephalitis, meningitis and epidural abscess. 5. Cortical abscess of the right kidney.

#### COMMENT

To understand properly the *modus operandi* in this case it is necessary to consider the anatomy of the region involved<sup>7</sup> along with the pathogenesis. As in all infected wounds the possible modes of spread of infection are by direct extension, by way of the venous drainage and by way of the lymphatic drainage. In my case probably only the first two modes of spread of infection operated, particularly that by direct extension. The lollipop stick penetrated the hard palate at the site of the orifice of the left pterygopalatine or posterior palatine canal about 2 cm. in front of the pterygoid process of the sphenoid bone near the alveolar margin.<sup>8</sup> This canal, which transmits the palatine nerve and vessels, is the caudal continuation of the pterygopalatine fossa, otherwise known as the sphenopalatine, sphenomaxillary or pterygomaxillary fossa (fig. 2). Each fossa has the shape of an inverted pyramid and is located deep among the bones of the face just below the apex of the orbit between the sphenoidal and maxillary sinuses. The size of the fossa is not constant, being relatively larger in infants and children than in adults. Dr. Warren B. Davis's specimens<sup>9</sup> show definitely that as the maxillary sinus, which is separated from the pterygopalatine fossa anteriorly by a thin septum, grows it encroaches on the anteroposterior diameter of this fossa.

The infection at the site of injury spread up along the fascial sheaths of the palatine nerve and vessels within the pterygopalatine canal to the fossa, where the inflammatory process became more extensive, causing the purulent material to accumulate within this potential space, finally forming a phlegmon of the pterygopalatine fossa. The complications that followed were due to the direct connection this fossa has by way of its fissures, canals and foramina with several important structures. The exudate spread through the infra-orbital fissure into the orbit, giving rise to a retrobulbar cellulitis.<sup>10</sup> This was clinically manifested by heat, redness and swelling of the lids and temporal region. The inflammation spread along the various fascial layers and muscles, becoming progressively worse during the next two days, and resulting finally in exophthalmos and fixation of the eyeball. Concomitant with this, the inflammatory process extended along the perineural sheath of

Fig. 2.—Specimen from an infant, illustrating the anatomy of the pterygopalatine fossa and paranasal sinuses. Sagittal section through the middle of the orbit; X, medial plate of the orbit removed to expose the frontal and ethmoid cells. P. F., pterygopalatine fossa; C, pterygopalatine canal; F, pterygopalatine foramen. (Illustration printed through the courtesy of Dr. Warren B. Davis and W. B. Saunders Company [specimen, series D, No. 251].)

cavernous sinus contained about 3 cubic centimeters of sero-sanguineous pus, which was also present in the left ophthalmic vein, but no thrombi were found. The other dural sinuses were normal. Pressure on the left side of the palate resulted in a profuse discharge of pus through the foramen rotundum from the pterygopalatine fossa and canal, which were filled with pus, into the perineural space of the maxillary nerve and into the middle cranial fossa. The left gasserian ganglion was soft, swollen and edematous as a result of the infection. The orbital plate was opened and the contents of the orbit were found to be edematous and hyperemic, with pus exuding. No pus was found in the paranasal sinuses. The exudates at the various sites looked identical.

The lungs were congested and had areas of edema on both sides, but no consolidation or abscesses were noted. The liver was swollen, soft, pale and hyperemic. The kidneys were pale and swollen and the capsules stripped easily. Small abscesses 2 mm. in diameter were present in the cortex of the right kidney, containing thick green pus. The remainder of the viscera were normal.

Plaque-like exudation of the cultures and smears taken from the pus found on the surface of the brain and the material exuding from the foramen rotundum, the ptery-

gopalatine fossa, through the foramen rotundum, an opening in the dorsal wall of the fossa, into the middle cranial fossa. Here there developed an inflammation of the semilunar or gasserian ganglion, from which the maxillary division of the fifth cranial nerve arises, as well as a localized meningitis.

clavicular joint, and over the sacrum, which were incised and drained. A thoracentesis done seventeen days after admission yielded 25 cc. of straw colored slightly turbid fluid which, when cultured, showed *Streptococcus haemolyticus*. On the twenty-third day after his admission the patient had a sudden massive hemoptysis and died.

This case apparently from the start was one of dual infection with a pneumococcus and a streptococcus, both of which in turn invaded the blood stream. The polyarthritides is noteworthy as a streptococcic manifestation here as in case 4, though in this instance it was purulent, whereas in case 4 it was a serous process which subsided

is, the fifth day of the disease), the broth culture showed a growth of *Streptococcus viridans*, the blood agar plates showing no growth. Another culture taken two days later as well as subsequent cultures were sterile. Unfortunately serial white counts were not obtained in this case, but on the day preceding the bacteremia the white cells numbered 12,900 with 90 per cent polymorphonuclears, of which 42 per cent were immature forms. Agglutinins for the infecting type of pneumococcus appeared on the twenty-fourth day of illness and persisted until his discharge, two months after admission. At this time dullness existed at the left base with decreased breath sounds and a few crepitant râles. A reexamination approximately one month later showed only decreased resonance at the left base; the patient was at this time symptom free.

#### *Streptococcic Septicemia Complicating Pneumonia*

Height of Bacteremia 500 colonies per cc. blood	Trend of White Counts Leukocytosis with shift to left in Schilling index	Local Complications Slight purulent effusion (sterile) on 8th day	Other Complications None	Outcome Death 16th day	Comment
Broths	Leukocytosis with shift to left in Schilling index	Empyema (type II pneu- mo.); 19th day lung abscess (Strep. haemo- lyticus)	Brain abscess (Strep. h.) and purulent meningitis (Strep. h.)	Death 59th day	Minimal bacteremia with extensive metastatic foci
80 colonies	Leukocytosis with shift to left in Schilling index	Lung section after death showed secondary Strep. haemolyticus infection	None	Death 13th day	Leukemoid blood picture
Broths	Leukocytosis with shift to left in Schilling index	None	Arthritis	Recovery	Minimal bacteremia long after crisis with recovery
100 colonies	Leukocytosis with shift to left in Schilling index	Delayed resolution	None	Death 29th day	
15 colonies	Leukocytosis with shift to left in Schilling index	None	None	Death 10th day	Dual bacteremia; <i>Pneumococcus I</i> and <i>Strep. haemolyticus</i>
10 colonies	Insufficient data	Pleural effusion (Strep. h.); repeated hemoptyses	Purulent polyarthritides (Strep. h.)	Death 23d day after admission	Dual bacteremia; pneumococcus unclas- sified and <i>Strep. haemolyticus</i>
Broths	Insufficient data	Delayed resolution	None	Recovery	Minimal bacteremia with <i>Strep. viri- dans</i> (only case in series)
12 colonies	Leukocytosis	Pleural effusion (Strep. h.); delayed resolution; secondary infection with <i>Strep. h.</i>	Arthritis; erythematous rash	Death 20th day	Dual bacteremia with <i>Pneumococcus I</i> and <i>Strep. haemolyticus</i>
Not stated	Leukocytosis	Secondary pneumonia of left lower lobe (Strep. h. ?)	None	Death 24th day	Patient developed a new pneumonia of opposite lung during observation
Not stated	Not stated	Serosanguineous empyema (Strep. h.); sputum bloody (Strep. h.) i.e. secondary infection with <i>Strep. h.</i>	None	Death 23d day	
Not stated	Not stated	None	None	Death 20th day	
Not stated	Not stated	None	None	Death 54th day	
7,600 colonies	Leukocytosis	Delayed resolution	Type I bacteremia with endometritis	Death 19th day	Postpartum pneumonia (type I) with bacteremia and endometritis with secondary <i>Strep. h.</i> ; septicemia
Not stated	Not stated	None	None	Death	

completely. In its extensive purulent metastatic lesions with only a minimal blood stream invasion it resembles case 2, for in both instances it was possible to isolate *Streptococcus haemolyticus* from the local pulmonary lesion and from the metastatic foci as well as from the blood stream. The cause of the repeated hemoptysis remains in doubt, since there was no necropsy.

CASE 8.—W. B., a white man, aged 51, admitted on the fourth day of the disease, showed type XIX pneumococcic lobar pneumonia of the left lower lobe. The temperature fell by lysis on the eleventh day, when he began to have an irregular intermittent fever, reaching a level of 101 F. and lasting for twenty-seven days. The physical signs and x-ray evidence during this time were interpreted to be those of delayed resolution. Repeated thoracentesis failed to disclose fluid, and culture of the lung juice on the tenth day was sterile. Blood culture on the day of admission was sterile. On the following day (that

This case warrants special mention because to our knowledge it is the first recorded case of postpneumococcic blood stream invasion with *Streptococcus viridans*, if one allows that the recovery of the organism in a single culture is sufficient evidence to warrant such a diagnosis. If so, it illustrates recovery from a transient minimal bacteremia occurring relatively early in the disease. It is interesting to speculate as to the possible relationship between the delayed resolution of the pneumonia and the finding of the streptococcus in the blood, since this organism, with its affinity for the interstitial tissue of the lung, might well predispose to the development of consequent organization. The absence of growth on the culture of lung juice five days after the positive blood culture would not necessarily rule out this possibility. In view of the frequent associ-

## SURGICAL PHOTOGRAPHY

Innumerable problems are associated with the technic of surgical photography. The small area of the operative field, the necessity of preserving asepsis, the masking of the field by assistants and nurses, and the inconvenience of delaying operation pending the adjustment of the apparatus are points that must be taken into consideration.

Because of its small size, speed and great depth of field, the miniature camera is the best suited of cameras for surgical photography. Larger cameras are somewhat more difficult to manipulate in the operating room but if properly used will give splendid results. A special assistant should be delegated to manipulate the camera during the operation, and he should have everything in readiness so that at the proper time the photograph may be taken without undue delay. Panchromatic or supersensitive panchromatic emulsions should be used exclusively.

Experimentation will be necessary with the particular camera and the light source that is to be used in order to determine the correct shutter speed and diaphragm opening for proper exposure and detail. Once the correct exposure is determined, all subsequent pictures are made under the same conditions. The camera should be brought as close to the operative field as is permissible.

The camera may be conveniently attached with clamps in a vertical focusing position to the crossbar of an ordinary therapeutic lamp standard. A long cable release will facilitate the taking of the picture. At the time a photograph is desired the surgeon or assistants step aside, the stand is wheeled into place with the camera directly above the field, the camera is lowered to the proper position, and the picture is snapped. The stand is wheeled away and the camera prepared for the next picture. In this manner the operation need be halted for only a few seconds during the taking of each photograph. A mark may be made on the lamp standard to indicate the proper position to which to lower the camera, or a pyramid iconometer may be mounted to the standard as suggested by Pierce.<sup>7</sup>

An ingenious method of surgical photography which does away with the lamp standard and permits the taking of pictures with the camera in the horizontal position is mentioned by Blumann.<sup>8</sup> An optical plane mirror about 3 feet square is moved about from point to point by a nurse while the photographer focuses on the image in the mirror. Practice and team work are necessary for proficiency in this method of working.

## THE PHOTOGRAPHY OF GROSS PATHOLOGIC SPECIMENS

Tissues fixed in Kaiserling's solution retain their natural color and are best suited for photography. There are, in general, two methods of photographing pathologic materials: first, supporting the specimen on a background and photographing directly; second, photographing after submerging the specimen in water.

The first method is satisfactory for most materials. A glass plate is supported a short distance from the floor, and a suitable background, contrasting with the color of the subject, is placed on the floor. MacCollum<sup>9</sup> suggests that the best color for a background is a light fawn color, which can be obtained by painting

a sheet of glass with light fawn colored paint, covering the painted side with another sheet of glass fixed to it by waterproof cement.

The specimen is moistened and placed on the glass plate. Illumination is obtained with two Photoflood bulbs in metal reflectors, one on each side. A diffusing screen made of tracing paper is placed in front of each reflector. The lamps are moved until sharp highlights are eliminated.

In taking the picture a small opening,  $f/16$  or  $f/22$ , should be used in order to insure adequate depth of field. The picture is best taken from above and the camera focused vertically. A tripod with a tilting top or an ordinary tripod equipped with an Optipod attachment will be found very convenient for vertical focusing. Wratten and Wainwright Panchromatic Plates, Eastman Portrait Panchromatic Films, Supersensitive Panchromatic and Panatomic roll films or other panchromatic emulsions should be used. Yellow filters  $K_2$ ,  $X_1$  and  $X_2$  may be found necessary to give a more accurate monochromatic rendering of the color. Contrast filters, green or blue, may be used to accentuate certain portions of the specimen. An orange filter, Wratten 15 or G filter, will give best results in photographing relatively colorless specimens such as heart sections. Visual examination of the specimen through various filters will indicate which filters if any are advantageous.

Sometimes very disturbing highlights are difficult to eliminate by the first method, and it may be necessary to immerse the specimen in a deep, flat-bottom dish filled with water.<sup>10</sup> Specimens fixed in Kaiserling's fluid should not be immersed in water or they will lose their color. Amyl alcohol or the preservative should be used. The bottom of the dish should be painted a suitable color to contrast with the material to be photographed. The lights are arranged and the photograph is made in the usual manner. This method is unsatisfactory for photographing lungs and other specimens containing air, because of the tendency of these specimens to float.

## COPYING

Plate and film pack cameras with double or triple extension bellows are admirably suited for copying on an enlarged scale. Cameras in which the bellows cannot be extended, such as ordinary roll film cameras, may be adapted to copying by employing a supplementary portrait or copying lens that increases the total focal length. In many cases a subject can be copied without a supplementary lens by bringing the camera as close as the distance scale will allow and by subsequently enlarging to the desired size on bromide paper.

A copying board will facilitate copying to a great extent. A suitable board consists of a flat base of wood at the end of which is attached an upright board for the support of the original. The camera is moved along the base board at right angles to the subject to be copied. The importance of absolute parallelism between the plane of the copy and the plane of the film cannot be emphasized too strongly. Copies of printed matter in which the lines of type converge and charts in which rectangular areas are no longer rectangular are due to failure in observing parallelism.

Even illumination may be secured by placing a light on each side of the copying board at the same distance from the subject. To eliminate paper texture and avoid glare from the surface of the copy, the line from the

count, appears to us to have distinct diagnostic importance, the value of this finding being further enhanced if serial counts have been obtained beforehand. In the absence of any positive clinical signs a blood culture should be taken in an attempt to establish the diagnosis.

The prognosis in this type of case is very unfavorable, as is evidenced by the reports of previous workers, all seven cases of *Streptococcus haemolyticus* septicemia reported hitherto having terminated fatally, whereas in our group six of the eight patients died. The factors that govern the prognosis in respect to the quantitative invasion of the blood are in doubt. Thus, while the recovered cases showed minimal invasion, it is obvious from our case reports that a fatal termination can nevertheless occur with a minimal degree of bacteremia—for example, case 2. In the main, however, the higher the bacterial count the more certain is the fatal outcome.

In conclusion, it might be well to deal with the possible portal of entry of this secondary invader. It would be of interest to know whether these patients harbored the organism in the upper respiratory tract previous to the onset of their pneumonia and whether the factor of lowered resistance permitted its spread from the latent focus. The report of Cole and MacCallum,<sup>11</sup> does not lend support to this theory; having found *Streptococcus haemolyticus* in the pharynx in a large number of cases of lobar pneumonia, they took cultures of the throats of pneumonia patients on admission to the hospital and at intervals during their stay. They discovered that the incidence of *Streptococcus haemolyticus* in these cases is increased during their stay in the hospital, the presumptive evidence being that they acquired the organism in the institution. This finding is of practical importance and stresses the need for isolation of pneumonia cases. In our series such contact infection cannot be ruled out, as no isolation measures were practiced.

Of additional interest is the question of the route which the organism follows in reaching the blood stream; that is, whether it invades the blood directly or whether it travels from the upper respiratory tract to the lung, whence it reaches the blood stream indirectly. The occurrence of local streptococcal post-pneumonic lesions is very common, and it may well be that the bacteremic cases represent a further stage, only the severer cases resulting in blood stream invasion. However, evidence is lacking to substantiate this speculation.

These reported cases show the great value of coordinated clinical and bacteriologic study as well as the need for keeping constantly in mind the possible invasion of the blood by this organism at a time when the patient's "resistance" is low and when he is harboring a local focus from which the streptococcus might gain access to the blood stream. For a more frequent recognition of complicating streptococcal infection, routine study of the bacteriologic flora of the upper respiratory tract, besides being informative, would be of distinct practical value. The need is also evident for more frequent blood cultures in late febrile complications of pneumonia.

#### SUMMARY

1. In eight cases of streptococcal septicemia occurring generally as a late complication of pneumococcal lobar pneumonia, seven were caused by *Streptococcus haemolyticus* and one by *Streptococcus viridans*.

2. The diagnosis of this complication is arrived at largely by a process of exclusion in which careful physical examination, roentgenologic evidence and thoracentesis are employed to rule out empyema or recrudescence of the pneumonia. Of diagnostic aid is a sudden increase in leukocytosis accompanied by an appreciable "shift to the left" of the Schilling count. The diagnosis is established by the finding of the organism in the blood culture.

3. The prognosis of this infrequent complication is poor except in cases showing minimal transient bacteremia, in which recovery may occur.

4. The rarity<sup>12</sup> of this complication is in our opinion more apparent than real and stresses the need for more frequent cultures of the blood in unexplained pyrexia following crisis in pneumococcal pneumonia.

309 West Nineteenth Street—115 East Sixty-First Street.

## SENSITIZATION TO MILK AS A RESULT OF ITS USE IN NONSPECIFIC FOREIGN PROTEIN THERAPY

CLARENCE BERNSTEIN JR., M.D.

AND

JULIUS E. GINSBERG, M.D.

CHICAGO

The increasing use of nonspecific foreign protein therapy, especially milk and its derivatives, prompts the report of an instance of untoward reaction to its administration and a few brief experimental observations on two such preparations.

#### REPORT OF CASE

*History.*—J. B., a German housewife, aged 24, entered the clinic complaining of asthma of two years' duration. There was no previous history of asthma in Germany or in Chicago until two years before admission, two years after her arrival in Chicago. There was, however, a typical history of seasonal hay fever of the fall type. The family history and past history were negative except for frequent colds and the loss of 35 pounds (16 Kg.) in two years.

*Examination.*—The patient was rather markedly undernourished. She breathed with difficulty and with an audible expiratory wheeze. There was mild cyanosis. The chest moved symmetrically, with considerable use of the accessory muscles of respiration. The trachea was in the midline. Resonance to percussion was slightly impaired at both lung apices and was accentuated at the bases. Rhonchi and wheezing were heard throughout. The heart was normal in size and outline. The rate was rapid; there were no murmurs. The systolic blood pressure was 104, the diastolic 54. The other observations were essentially negative.

Wassermann and Kahn tests gave negative results. Hematologic examination gave results within normal limits. There was no eosinophilia. The sputum was negative for *Bacillus tuberculosis* on several occasions, both by direct smear and on concentration. The urine was normal.

Skin tests, largely by the scratch method, the remainder intracutaneous, revealed positive reactions to the pollens of trees, grasses and weeds, and to asparagus, banana, orange, potato and pyrethrum. There were several "dubious positives" of probably little significance. The reactions were negative to

12. A search of the records of Bellevue Hospital for the past ten years was made by one of us (S. S.) following the preparation of this paper. The investigation revealed ten additional cases of this complication among approximately 3,500 cases of pneumonia. We believe that this is far from representing the total number, as it is our impression that a large number of cases have been unrecognized.

From the Department of Medicine, Sections of Allergy and Dermatology, the University of Chicago.

The authors are indebted to Dr. K. Reuter of the Section of Allergy and to Dr. S. W. Becker of the Section of Dermatology for cooperation.

11. Cole, Rufus, and MacCallum, W. G.: Pneumonia at a Base Hospital, J. A. M. A. 70: 1146 (April 20) 1918.

where two different colors predominate, it is usually necessary to render the fullest possible detail in one of the colors, making the other color stand out in sharp contrast. Where detail within a certain area is desired, the rule is to use a filter of the same color; where contrast between the area and its surroundings is desired, one should use a filter of a color complementary to the color of the area to be rendered dark in the final print. For example, if a hematoxylin-eosin stained slide is photographed through a red filter, the blue stained sections will be rendered very dark and will stand out in sharp contrast against the red stained sections. If a green filter is used, the red areas will appear almost black in contrast with the green areas, which will be rendered relatively lighter. The best way of determining the correct filter to use is to examine the object visually under the microscope with various filters until the contrast and detail are satisfactory. Filters may be obtained in any color, depending on the character of the stains used. To obtain extreme contrast for acid fuchsin, Wratten B and G filters should be used; for eosin, the G and H filters; for hematoxylin, the B and G filters; and for methylene blue, the D and G filters.<sup>12</sup> These recommendations are for obtaining maximum contrast between the stained area and its surroundings and not for detail within the area so stained. These filter combinations render the color of the stain for which they are recommended very dark. This is not always desirable, since by increasing contrast there is often a marked loss of detail. Gelatin filters must be mounted for permanence between two glass plates with Canada balsam. The filter when in use is usually placed between the light source and the microscope. In this position, optically perfect glass is not required for the mounting of the filter.

Filters may be conveniently made from old photographic films and some stains. A simple method of making filters is described by Stern.<sup>13</sup> Several unexposed films are placed in acid hypo to remove the silver emulsion; the films are then washed and dried. For a blue filter the film is placed in alcoholic or aqueous methylene blue. For "in-between" colors, the film is placed in two stains; e. g., for a green filter, stain in picric acid, wash, stain in methylene blue, wash and dry. The film may then be mounted between glass plates with Canada balsam. Quoting Mallory and Wright, Stern gives the following formula for a general filter to be used with eosin-methylene blue (Giemsa and Romanowski stains), alum-hematoxylin and eosin, phosphotungstic acid hematoxylin stain, Gram-Weigert, and carbolfuchsin stains: copper sulfate, 175 Gm.; potassium bichromate, 17 Gm.; sulfuric acid, 2 cc.; distilled water to make 500 cc. Use in a flat glass cell and seal to make air tight.

#### SPECIALIZED PHASES OF PHOTOGRAPHY

**Ocular Photography.**—Photography of the eye is divided into two branches: photography of the anterior segment of the eye, and fundus photography or retinography.

Any good camera will provide satisfactory pictures of the external eye, provided focusing is exact and illumination ample. A ground glass focusing back is ideal but not absolutely necessary. If no double extension is provided for in the bellows, a supplementary portrait attachment may be used. Photoflood lamps provide

suitable illumination. Miniature cameras are well adapted to this type of photography.<sup>14</sup> The camera may be used in conjunction with a corneal microscope mounted on it by means of an adapter.<sup>15</sup> Panchromatic or supersensitive panchromatic emulsions are most frequently used, but if colored pictures are desired the various additive color materials (see "Color Photography") may be used.<sup>16</sup> Infra-red rays are able to penetrate opacities of the cornea, and plates sensitive to infra-red light (see "Infra-red Photography") will, in an eye with a completely opaque cornea, allow the study of the state of the pupil, the presence of synechiae, and defects of the iris.<sup>17</sup> For stereoscopic pictures of the external eye the Bausch and Lomb stereoscopic anterior segment camera is perhaps the most satisfactory. The Amsler Photo Keratoscope<sup>18</sup> permits the photography of the image of the Placido disk reflected on the anterior surface of the cornea. Photography of the angle of the anterior chamber—goniophotography—is possible by means of the technic described by Castroviejo.<sup>19</sup>

For photography of the fundus a special type of camera is needed, and the Nordenson retinal camera is probably the most popular one in use. The conditions required for retinography are a pupil that can be dilated, transparent media and a means of adequately fixating the eye. Black and white photography is a simple matter, but color fundus photography offers special problems, since exposing the retina for long periods to the powerful arc light of the Nordenson camera is deleterious to the retina. Mann<sup>20</sup> describes a satisfactory technic for color fundus photography which corrects many of the previous shortcomings. By applying a Wessely fixation apparatus to the Nordenson camera, stereoscopic photographs of the fundus may be taken. The subject of stereoscopic photography has been reviewed by Bedell<sup>21</sup> in a recent article. Infra-red photography of the fundus has been shown to offer no special advantages.

**Gastroscopic, Stomatoscopic, Laryngoscopic, Proctoscopic and Cystoscopic Photography.**—Photography of the stomach, pharynx, larynx, rectum and bladder is sometimes of considerable aid in the diagnosis of obscure conditions. Two types of instruments are generally used for endoscopic photography. In the first type a tiny camera is introduced into the body cavity and a photograph is taken more or less blindly. This method is rather haphazard and a number of photographs are usually required, the element of chance determining the inclusion of the pathologic lesion on the emulsion. In the second type an endoscope is used to inspect visually the body cavity, and, when the lesion has been located, a special camera is attached to the endoscope and the photograph is taken. This method is by far the preferable one but is associated with a number of technical problems, including the difficulty of getting sufficient illumination. The introduction of filament lamps of great intensity and the

the literature. The injuries sustained are ordinarily merely abrasions or at times more extensive local reactions, but, as in my case, they may lead to serious complications. There are numerous ways in which this may happen. An infection at the site of injury may spread by direct extension into the soft tissue, giving rise to a localized phlegmon. Such an infected wound in the posterior pharyngeal wall may result in a retro-pharyngeal abscess with subsequent development of mediastinitis, pneumonia and death.<sup>2</sup> Likewise, an infection in the region of the nose may result in a sinus thrombophlebitis as a result of venous spread of the infection.<sup>3</sup> Should the injury occur at the orifice of a canal or at a foramen of the skull, as in my case, the infection may spread along the fascial layers of the nerves or vessels, giving rise to a phlegmon within some potential space in the skull or within the cranial fossa itself. Besides this, injury to the palate may result in necrosis of the site of injury or the foreign body may perforate the palate. The stick may penetrate the posterior or posterolateral wall of the pharynx and enter the cranial or spinal space, giving rise to a purulent meningitis or even an injury to the cerebellum.<sup>4</sup>

Once an injury is sustained it should receive the same prompt and thorough care as any other puncture wound, thus avoiding complications.<sup>5</sup> If an abscess or phlegmon results, an attempt should be made to institute adequate surgical drainage.

In addition to the fatal injury with the lollipop stick the case reported here is of interest because of the presence of a phlegmon of the pterygopalatine fossa with its many diverse complications as a result of the spread of the infection through the various channels of this fossa and by way of the venous drainage. A phlegmon of this fossa may arise as a result of other causes besides an injury to the hard palate, as noted by Ullmann<sup>6</sup> in adults, who reported several cases associated with injections of the sphenopalatine ganglion. Thus a phlegmon of the pterygopalatine fossa may develop as a result of infection spreading from the nose, the paranasal sinuses or the ocular orbit.

#### REPORT OF CASE

**History.**—F. D., a boy, aged 22 months, was admitted to Morrisania City Hospital May 4, 1935, because of persistent fever, rhinitis, marked anorexia, apathy and drowsiness of three days' duration. The child's mother volunteered that he was never ill prior to this date. However, after close questioning, she recalled that on April 23, eight days prior to the onset of these symptoms, the child fell down with a lollipop in his mouth, causing the sharp stick to penetrate the candy and injure his mouth. The child cried at this time, but no bleeding or site of injury was noted by the parents. The familial and developmental histories were irrelevant.

**Physical Examination and Progress.**—On admission the child was pale and acutely ill, with a temperature of 103.8 F. However, he was well nourished, weighing 29 pounds (13 Kg.). His skin was warm, dry and of fair turgor. The lymph nodes were not palpable. The heart and lungs presented no abnormalities. The abdomen was soft and depressed, and no masses or viscera were palpable. The extremities and genitalia were normal. Examination of the mouth revealed a small abrasion on the lateral aspect of the hard palate near its junction with the soft palate on the left side, but no definite swelling or induration was noted. Probing in this area revealed no sinus tract, but a sanguineous material exuded on one occasion. The tongue and pharynx were dry and coated. Both ear drums were normal. Examination of the nose revealed no exudation or congestion or any other evidence suggestive of a sinusitis. The eyes were freely movable, the pupils reacted to light, and no inflammation, edema or exophthalmos was present. The eyeballs were normal. Neurologically he manifested markedly depressed reflexes but no palsies, abnormal reflexes or signs of meningeal irritation.

A spinal tap was performed and the fluid was found to be under pressure of 12 mm. of mercury. On examination the sugar was found to be normal, but there was no globulin present and the cell count showed 80 cells per cubic millimeter, all of which were lymphocytes. No organisms were found on smear and culture. The blood count was 36,800 white blood cells with 89 per cent polymorphonuclear leukocytes, 5 per cent lymphocytes and 6 per cent monocytes, with 5.1 million red blood cells and 90 per cent hemoglobin by Sahli. The blood culture was sterile. The urine was acid with a specific gravity of 1.018 and contained a trace of albumin and 2 plus acetone but no sugar.

At this time the child was thought to have an encephalitis because of the lack of definite physical manifestations, fever, drowsiness and hyperirritability and the spinal fluid changes, as well as the fact that a mild epidemic of poliomyelitis was prevalent at that time. There was a difference of opinion in the service as to the relation of the injury to the palate to the prevailing condition in the child. The injury appeared to be a clean healing abrasion, so that surgical intervention was not deemed necessary at this time. Because of the dehydration the child was given on the day of admission two clyses of 5 per cent dextrose in saline solution, in all 850 cc. During the night a swelling of the left eyelids began to develop, and the next day, May 5, there was a definite swelling of both lids of the left eye especially involving the temporal side of the upper lid and extending out to the face. The conjunctivae were injected and everted. The temperature of the child during this day varied from 103 to 106 F.

May 6 the child's general and ocular condition grew much worse. There was marked increase in the edema of the left eyelids, extending out into the temporal region of the head. The swelling was very tender and red. There was also a marked chemosis in this eye, with complete fixation of the globe. The eyegrounds, however, were perfectly normal. Further examination revealed that the child was markedly hyperesthetic and irritable in spite of being drowsy. There was a tremor of the right upper extremity, but no definite convulsion or paralysis was noted. However, careful examination of the motor and sensory status was not possible. The child's temperature was maintained at 106 throughout the day. A

Fig. 1.—Types of lollipop sticks.

spinal tap was done again on this date, revealing clear fluid under normal pressure with 120 cells per cubic millimeter of fluid, 100 per cent being lymphocytes. The sugar and the globulin were present in normal quantities.

It was obvious at this time that the child was suffering from a spread of infection from the palatal injury and it was thought to be probably by way of the venous drainage. The abnormalities in the spinal fluid were interpreted as due to a sympathetic meningitis.

Roentgen examination of the nasal accessory sinuses revealed moderate cloudiness of the left maxillary sinus and slight cloudiness of the ethmoid cells on this side. There was a question whether the cloudiness was due to soft tissue infiltration over this area or to actual pathologic changes within the sinuses.

During the day the orbital cellulitis grew progressively worse and an incision and drainage was attempted through the ethmoid cells at the inner canthus of the left eye, but no pus was found. The child returned to the ward in fair postoperative condition and a continuous intravenous infusion was given for a short time.

It is beyond the scope of this paper to detail the theoretical and technical aspects of clinical movie making. The general principles of clinical photography in reference to backgrounds, illumination, filters, and so on, apply equally to clinical cinematography. For eye surgery the illumination obtained from a Bausch and Lomb ophthalmic operating lamp will be found satisfactory. Motion pictures of the fundus may be obtained with some degree of success by attaching the camera to the Nordenson apparatus in place of the plate holder.<sup>26</sup> Motion photomicrography by means of panchromatic emulsions or Kodachrome opens up new fields in the study of living organisms. The camera and the microscope must be mounted on completely separated supports to insure stability, since the motor drive unit is a source of constant vibration. A special viewing device is required for the focusing of the microscope and selection of the proper field.

The Ciné-Kodak Special is a perfected 16 mm. motion picture camera that has definite advantages, including a variable shutter and a reflex finder that permits accurate focusing regardless of the focal length of the lens used or the distance between the subject and the camera.<sup>27</sup> A complete battery of lenses is available, from 15 mm. for wide angle work to 6 inches for telephotography. Fades, dissolves, double and multiple exposures, and single frame exposures can be made, and various masks can be used. The film chambers of 100 and 200 feet are interchangeable and the camera is geared for speeds varying from 8 to 64 frames a second. The camera appears to satisfy the most exacting scientific requirements, and the results are comparable to those obtained with more expensive professional movie machines.

## THE PHARMACOPEIA AND THE PHYSICIAN

### THE USE OF ADSORBENTS IN GASTRO-INTESTINAL DISEASES

EDWARD S. EMERY JR., M.D.  
BOSTON

*This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and will be published in book form when completed.—Ed.*

Adsorption is such a complicated subject that it is useless to discuss the physicochemical theories. Yet some information about the basic characteristics of adsorbents is necessary if one is to use them intelligently. Adsorption is defined as the attachment of one substance to the surface of another. It is essentially a property of colloids, those substances which have large sized molecules and which make up a large part of the biologic world. Protoplasm is a colloidal substance, and therefore the behavior of biologic processes cannot be separated from the property of adsorption.

In addition to this, the subject is complicated further in that adsorption is influenced by electrolytes such as the acids and their salts. Kaolin shows a high degree

of adsorption in an acid medium and will release the same substances in an alkaline medium. Pharmacists have made use of this property by incorporating kaolin with the alkaloids. By this means the drugs are adsorbed more slowly after they have entered the alkaline intestine.

Hence the therapeutic use of adsorbents in the gastrointestinal tract involves a complicated interaction of compounds, the results of which often cannot be fully predicated on test tube experiments. Numerous substances occur in the intestinal tract which are susceptible to modification by adsorption. They include the normal secretions such as mucus and the ferments, metabolic products, and food substances or their products of digestion. The interaction of these products with adsorbents is influenced by the electrolytes such as hydrochloric acid and its salts, sodium carbonate, sodium bicarbonate, and bile salts. Finally, there may be present bacteria and bacterial toxins, or toxic products of protein digestion, the removal of which is usually the aim of the therapeutic use of adsorbents.

Although the physician may desire to remove or render harmless the latter substances, one cannot be sure that the object of medication will be fulfilled or that only desirable effects will be obtained. So little study has been made of the effect on giving adsorbents to animals that their use at present depends in large measure on empirical reasoning and the effects that have been observed in vitro. Therefore the physician who uses adsorbents is entering a field of therapeutics in which the pitfalls are not clearly indicated and the usefulness of which has not been definitely defined.

#### ADSORBENTS IN CLINICAL USE

Although many substances exhibit some qualities of adsorption, only charcoal and kaolin have been utilized in medicine to any extent, because of their adsorptive characteristics. Charcoal is an excellent adsorbent, and industrial chemists use large quantities. It has a strong affinity for gases when dry, and it is said that charcoals that wet by water easily exhibit adsorptive capacities for small amounts of impurities superior to those resistant to wetting.<sup>1</sup> It will adsorb various kinds of organic acids and drugs.<sup>2</sup> Dingemause and Laqueur<sup>3</sup> found that charcoal would remove mercury salts and strychnine from the wall of the stomach to which they had adhered and could be removed with the charcoal. Becher<sup>4</sup> states that charcoal will remove all the products of intestinal putrefaction from urine shaken with it. Takahashi,<sup>5</sup> who studied the effect of adsorbents on the poisonous action of alkaloids on excised rabbit's intestine, states that charcoal is more effective than kaolin in preventing the poisonous action.

Various investigators have reached different conclusions about the relative efficiency of charcoal made from plant and animal sources.<sup>6</sup> More recently, acti-

encephalitis and epidural abscess. The spinal fluid response was that of a sympathetic or acute serous meningitis, further indicating that the meningeal inflammation was localized. The tremors of the right upper extremity were due to this inflammatory involvement of the motor area of the left cerebral cortex.

There probably was present in the early course of the illness an endophlebitis of the pterygoid plexus of veins, which was responsible for the sepsis and the metastatic abscesses in the kidney. The infection had probably spread by way of the venous drainage of the palate as well as from the pterygopalatine fossa phlegmon. This plexus<sup>3</sup> is connected directly with the cavernous sinus by communicating vessels and through the inferior ophthalmic veins, which also send large communicating branches to the pterygoid plexus. The ophthalmic vein and the cavernous sinus endophlebitis on the left side extended directly from the pterygoid plexus endophlebitis or developed subsequent to the orbital cellulitis. Obstructive thrombosis of the cavernous sinus did not exist. The other dural sinuses were free of involvement.

The sphenopalatine ganglion,<sup>11</sup> which is the second largest nerve center in the head and the largest outside of the cranial cavity, is one of the most important structures within the pterygopalatine fossa. The ganglion was markedly inflamed along with the remainder of the contents of the pterygopalatine fossa.

When a diagnosis of pterygopalatine fossa phlegmon is established, whether as a result of injury to the palate or other causes, the proper procedure is to establish surgical drainage of the fossa. This may be accomplished when a thin exudate is present by an incision over the pterygopalatine foramen, allowing drainage through the pterygopalatine canal. The fossa may be more thoroughly drained directly through the posterior wall of the maxillary sinus by way of a Caldwell-Luc approach to this sinus.<sup>12</sup> A still more extensive operation would be to remove the zygomatic arch and enter the fossa by way of the pterygomaxillary fissure, its lateral boundary, as described by Frazier.<sup>13</sup> In the case described the inflammatory process had already established itself in the orbit, the cranial cavity and the venous channels of the head by the end of the first day in the hospital, so that the incision and drainage of the orbit attempted on the second day was useless. The illness proceeded rapidly to a fatal termination, indicating the virulence of the invading organism and the ease with which an infection in the pterygopalatine fossa can spread.

#### CONCLUSION AND SUMMARY

Following an injury to the hard palate by a lollipop stick in a boy aged 22 months, the infection spread from the palate along the pterygopalatine canal to the pterygopalatine fossa, with the formation of a phlegmon. Subsequently the infection spread to the orbit and the middle cranial fossa and gave rise to an orbital cellulitis, localized purulent meningitis, encephalitis and epidural abscess. An endophlebitis of the veins draining the area also was present. Symptoms first appeared eight days after the accident, death ensuing six days later.

The fossa was in direct connection with the middle cranial fossa, the orbit, the nasal cavity, the palate and the pterygoid, infratemporal and infra-orbital regions of the face. Infections within this fossa are of great potential danger because of its anatomic relationships to important structures.

There are various complications that may arise as a result of foreign body injuries within the mouth. Injuries to the mouth by lollipop sticks, although usually innocuous, may at times result in serious complications or even death. In view of the extensive use of lollipops among children it is a common practice for them to run about with one in their mouths. This should be discouraged in view of the potential dangers involved. Lollipops with sharply pointed sticks should be forbidden at all times. All injuries within the mouth should receive immediate and thorough attention.

### PRACTICAL CLINICAL PHOTOGRAPHY

LEWIS R. WOLBERG, M.D.

KINGS PARK, N. Y.

(Concluded from page 118)

#### INFRA-RED PHOTOGRAPHY

The development of emulsions sensitive to the infra-red portion of the spectrum has introduced a new phase of clinical photography, for, as Massopust<sup>5</sup> has pointed out, the reflection properties of the skin for infra-red light differ from those for visible light, and detail below the surface is apparent where visible light does not penetrate.

The limited work which has been done with infra-red emulsions in medicine indicates that the method is chiefly applicable to the study of some skin diseases, the superficial venous system, gross pathologic specimens and, to some extent, photomicrographs.

The most popular infra-red material in use is the Eastman Infra-Red Sensitive Plate, Type 1-R. This plate is sensitive to violet and blue light; hence it is essential to exclude this light by means of a filter such as the red Wratten A filter. Infra-Red Sensitive Film Type 1-R also is available in 35 mm. film in daylight loading magazines for use with miniature cameras. Infra-red materials must be handled in total darkness in loading plate holders and in developing, or a special safelight such as the Wratten No. 3 Safelight must be used. Plate holders equipped with metal slides or with special hard rubber slides opaque to infra-red rays are necessary.

Illumination is obtained with two Photoflood bulbs in a reflector. With the light a distance of 3 feet from the subject and a diaphragm opening of f/22, an exposure of five seconds is necessary. With four Photofloods, an exposure of three seconds at f/22 or one second at f/11 will suffice.

Infra-red photography is especially suitable for varicose veins and other disorders of the superficial venous system. Most of the infra-red photographs of skin lesions have shown what might be termed negative results; that is, details visible to the eye and recorded in a visible light photograph are invisible in the infra-red picture. This apparent disappearance of the lesion is of value in cases of lupus and similar conditions under treatment with ultraviolet rays, since it makes it possible to visualize the progress of healing under the thick scab formed and also reveals the presence of enlarged veins in the lesion.

In photomicrography of histologic specimens stained with the usual dyes, the use of infra-red sensitive materials is not generally recommended, since most of the dyes used are transparent in this portion of the spectrum. It is of value, however, in photographing silver impregnated specimens, making those portions which have taken up the silver stand out in bold relief.<sup>6</sup> It is also of value in photomicrography of insects that possess a chitinous exoskeleton, since the infra-red rays readily penetrate this substance, revealing the nature of the innermost structure.

is unlikely if doses of kaolin are used which are no greater than are prescribed ordinarily for man. Golob<sup>15</sup> reports a case of frank bleeding from the intestine as a result of hard concretions from barium sulfate which apparently had become embedded in the mucosa. The Germans<sup>16</sup> are said to have discontinued the use of kaolin during the war in the treatment of dysentery because of the development of fatal perforations.

Although large doses are usually indicated, their danger should be remembered.

#### THE THERAPEUTIC USE OF ADSORBENTS

*The Diarrheas.*—Adsorbents have been advocated for diarrhea and, as previously pointed out, kaolin was used in China for this purpose long before it was recognized in the Western world. Its apparent success in the treatment of cholera suggests its possible usefulness in the treatment of other diarrheas. Unquestionably it seems to have a beneficial effect in certain cases, but there are no exact indications for its trial. A judicious use of a drug requires an exact knowledge of its pharmacologic action, which we do not possess about kaolin. Moreover, there are many incidences of diarrhea in which the exact cause cannot be determined.

There seems no reason to expect results on patients whose diarrhea is occasioned by nervousness, exophthalmic goiter or fat intolerance. Conditions like pernicious anemia and amebic dysentery must be suitably treated with such preparations as liver and the antiamebic drugs. The adsorbents are contraindicated in cancer and deficiency diseases. For the ordinary acute attacks of diarrhea the usual treatment with bismuth preparations and opium prove satisfactory, and for diarrheas due to specific agents such as worms the appropriate treatment can be instituted.

However, substances such as kaolin are worthy of a trial in patients suffering from severe food poisoning or from an infection with a dysenteric organism. These patients have a moderately or markedly high temperature. They may have fifteen or more watery stools with or without the passage of blood or pus, and they become severely dehydrated. The following regimen seems best fitted to cope with this type of condition: The loss of fluids must be made up by the use of salt solution either intravenously or, if the facilities for intravenous injection are lacking, by hypodermoclysis. The amount of solution to be given must vary with the needs of the patient, but between 1 and 3 liters in the twenty-four hours is usually indicated. All food should be stopped for a period of one to two days, during which time kaolin is given. To be effective, large doses are required, and from 50 to 100 Gm. of kaolin should be administered in water every three hours until the number of movements has begun to lessen; then the amount at one dose may be decreased, and the interval increased between doses, according to the judgment of the physician in charge.

*Treatment of Idiopathic Ulcerative Colitis.*—Kaolin has been used in the treatment of idiopathic ulcerative colitis to the satisfaction of some clinicians. However, there are few reports on its use in this disease, and the results do not appear as striking as in the type of case already described. Its theoretical value in idiopathic ulcerative colitis may be twofold; namely, the adsorp-

tive effect on bacteria and toxins in the colon and the production of formed stools. In a severe case of ulcerative colitis the colon has lost much if not all the function of absorption, and one would not anticipate the same constipating effect as with a normal colon, in which these claylike substances will give up their water very completely. Regarding the "detoxifying action" of these substances, there is also a considerable difference between the situation involved here and in other infections of the tract. In the ordinary food poisonings, for example, the infection is found throughout the small intestine, as contrasted with ulcerative colitis, in which most of the lesions are in the colon. In the former group the adsorbent has a chance to act shortly after ingestion, whereas in ulcerative colitis the material must traverse the length of the small intestine before reaching the troubled area. During this passage it seems probable that most of its beneficial properties will be lost. One would not expect to obtain results unless a large enough excess is administered to permit kaolin to reach the colon in a state capable of exerting an adsorbent influence. Such an excess over any length of time involves the danger of removing vitamins and other substances essential to the individual. Hence it seems probable that the potential dangers offset the potential value of this medication in ulcerative colitis.

*Diverticulitis of the Colon.*—Kaolin and barium sulfate have been used in diverticulosis of the colon with some reported benefit. These apparently successful results have been explained on the basis of filling the pockets with inert substances and in this way preventing the accumulation of irritating products. This explanation does not seem very convincing, and I have tried both kaolin and barium sulfate in a few patients with diverticulitis without satisfactory results. There is another group of patients with diverticulosis who have transient attacks of diarrhea. These patients do not give evidence of inflammation, either subjectively in the way of pain or objectively in the way of spasm, when observed by the roentgen ray. One is unable to give an adequate explanation for the diarrhea, and it is possible that this is the type of case of diverticulosis in which the adsorbents are said to give good results. Any effect which the adsorbents have on this kind of diarrhea can be explained best by the idea that they facilitate drying of the stools. One should avoid prescribing these inert substances in the presence of a diverticulitis, because the danger of a perforation or obstruction is a real one.

*The Dyspepsias.*—Unfortunately, so little is known about the cause of dyspeptic symptoms that a rational approach to the subject is difficult. However, a word of caution should be spoken of them because adsorbent drugs, particularly charcoal, have been administered for dyspeptic symptoms in the past. Because dyspeptic symptoms may come from the presence of organic disease anywhere in the body, all patients suffering from these symptoms should have thorough examinations. After the presence of organic disease has been ruled out, the commonest cause is nervousness. Its recognition and treatment are essential if one is to obtain satisfactory results. Palliative medication may be of value during the course of treatment and all physicians see a certain number of individuals complaining of gastric-intestinal symptoms for which no adequate explanation can be given.

lights to the center of the copy should form an angle of 45 degrees with the camera axis. Photoflood bulbs are convenient sources of light. A lens hood will help prevent glare on the surface of the lens.

In roll film cameras, when portrait or copying lenses are used, it will be necessary to restandardize the distance scale of the camera. To do this the back of the camera should be removed and a piece of ground glass placed in the camera back. The diaphragm of the camera is opened wide, the subject brought into sharp focus, and the position of the camera on the base board noted. By varying the bellows extension and distance of the lens from the subject, the size of the image seen on the ground glass or tissue paper will grow larger or smaller. The distance of the camera from the subject, the position of the bellows as indicated by the distance scale, and the area included on the ground glass may be plotted for future reference. By making a chart of these three factors, any subject may be copied directly without preliminary focusing on ground glass.

To copy x-ray films, the film is placed in an ordinary viewing box and copied directly. Relatively large x-ray films will obviate the necessity of using a copying lens, and the photograph may be taken as close to the x-ray film as possible without the supplementary lens. In the event that a viewing box is not available, the film may be attached to a window and the picture taken by daylight. Some diffusing material should be placed behind the roentgenogram to prevent indistinct images of trees, buildings or other objects showing. The use of a large scale film is imperative, since process film and commercial film yield negatives of such high contrast that they cannot be printed. Roentgenograms may be reproduced as "positive" or "negative" images or as facsimiles.

Exposure is, of course, a matter of experience, and once the correct exposure is obtained good copying can easily be standardized. In copying, small diaphragm openings, such as  $f/16$  or  $f/22$ , should be used, although preliminary focusing must be done with the diaphragm wide open. Process films and plates will insure the best contrast in copying line subjects in which all the tones are reproduced as an intense black or pure white, such as charts, printed matter or graphs. A hydroquinone-caustic developer<sup>3</sup> will insure the highest degree of contrast. The contrast may be further exaggerated by reducing the negative with Farmer's reducer and subsequently intensifying it with intensifying solutions.<sup>3</sup> In full scale subjects in which all the tones must appear in the copy with the same gradation as in the original, as roentgenograms, photographs or pencil sketches, it will be necessary to use a long scale film.

#### PHOTOMICROGRAPHY

Minimum requirements for photomicrography are a microscope, a source of light, a camera, and several color filters. The microscope should be equipped with a substage condenser and preferably with a mechanical stage. A suitable light source is the Mazda C, 6 volt, 108 watt T 10 bulb or Pointolite lamp. Less expensive light sources are ordinary 100 or 200 watt frosted bulbs. If a more intense light is necessary, Photoflood bulbs may be used. Whenever intense light sources are employed, a heat absorbing filter should be placed between the microscope and the light. This filter may consist of a 2 inch water cell or of a sheet of special heat absorbing glass, such as Alko-glass.

It is essential that the microscope and camera be centered in one axis, with the plane of the stage on

which the slide rests parallel to the plane of the film or plate. A piece of black cloth, one end wound around the camera lens and the other end wound around the microscope, will prevent the intrusion of extraneous light. The assembled apparatus must be rigid and vibrationless. The most simple assemblage is a horizontal axis with the microscope tilted to a horizontal plane and the slide and film in a vertical plane. However, in many cases a vertical set-up will be necessary, and some means must be used to support the camera in a vertical plane.

The simplest method of making microscopic pictures, especially applicable to roll film and miniature cameras,<sup>11</sup> is by focusing for visual observation and then placing the camera, with the distance scale set at infinity, in line with the axis of the microscope. A light-tight connection between the lens and the ocular should be utilized. If the photographer customarily wears eyeglasses for corrective purposes, he should wear these while doing the preliminary focusing.

In cameras with double extension bellows and a ground glass back, the technic is somewhat different. The lens should be removed from the camera and the ocular of the microscope should be placed inside the shutter. Focusing is then accomplished directly on the ground glass. For greater accuracy in focusing, a magnifying glass should be used over an 18 mm. cover-slip which has been cemented to the ground glass with Canada balsam. If much photomicrography is contemplated, it may be advisable to invest in a special optical bench, which insures a minimum of vibration and a maximum of ease in manipulation.

*Adjustment of Apparatus.*—In addition to obtaining rigidity in the complete assembly, it is necessary to obtain an accurate centering of the light. The light source may be set in line with the microscope and camera, or the mirror may be used for reflecting the light into the microscope. The substage condenser must be focused accurately in order to obtain the best possible distribution of light. The iris diaphragm should be closed down until the desired contrast is gained, and one should bear in mind the fact that a too large iris opening will reduce contrast. The inside of the microscope body tube should be examined and if reflections are seen they must be reduced by placing black paper around the inside of the barrel.

*Emulsions.*—Best results will be obtained with a panchromatic material. Eastman Portrait Panchromatic Film, Panchromatic Process Film, Panatomic Film, Supersensitive Panchromatic Film and Wratten M Plates all have characteristics that are suited for special types of work. The emulsion should be chosen to compensate for the contrast of the subject. Thus a very contrasty subject will require a soft material, while a flat, noncontrasty subject will be better reproduced by using a contrasty emulsion. Cameras using roll film may confine themselves to one material, such as Panatomic film, since filters will adequately control contrast and detail. Exposure depends on the intensity of light and the degree of magnification. The only method of determining the correct exposure is by experimentation, and exposures should be recorded for future reference. The procedures for the processing of the film, printing and enlarging are the same as for other pictures.

*Color Filters.*—The use of color filters is extremely important in photomicrography. In a stained slide

11. Morgan, W. D.: Micro and Macro Photography with the Leica Camera, *J. Biol. Photograph.* A. 1: 92-98 (Dec.) 1932.

that injury might result. The Council decided that until it is proved satisfactorily that the feeding of psyllium flour over long periods of time is not injurious, it would not accept any preparation containing psyllium flour.

The Council declared Carasyl Plain, Carasyl with Cascara, and Carasyl with Aloin and Cascara unacceptable for New and Nonofficial Remedies because they are marketed with unsubstantiated therapeutic claims and under a proprietary name.

## NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

### PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1936, p. 67).

The following dosage form has been accepted:

*Sterile Ampoules Procaine Hydrochloride Crystals For Spinal Anesthesia, 50 mg.*

### SCARLET FEVER STREPTOCOCCIC TOXIN, U. S. P. (See New and Nonofficial Remedies, 1936, p. 388).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

*Scarlet Fever Streptococcus Toxin for Immunization-Mulford:* Prepared by the method of Drs. Dick under U. S. Patent 1,547,369 (July 29, 1925; expires 1942) by license of the Scarlet Fever Committee Incorporated. Marketed in packages of five ampoule-vials containing, respectively, 500, 2,000, 8,000, 25,000 and from 80,000 to 100,000 skin test doses; also in packages containing ten complete treatments consisting of six 10-cc. vials, one containing 500 skin test doses per cubic centimeter, one containing 2,000 skin test doses per cubic centimeter, one containing 8,000 skin test doses per cubic centimeter, one containing 25,000 skin test doses per cubic centimeter and two containing from 80,000 to 100,000 skin test doses per 2 cubic centimeters.

### PERNOSTON.—Butyl-β-bromallyl barbituric acid.—5-(butyl-2)-5-β-bromopropenyl malonylurea.—[CH(CH<sub>2</sub>)CH<sub>2</sub>CH<sub>2</sub>](CH<sub>2</sub>-CBr:CH<sub>2</sub>)C-CONH-CONH-CO. Pernoston differs from

barbital (diethylbarbituric acid) in that both of the ethyl groups of the latter are replaced, one by a (normal) secondary butyl group, and the other by a substituted brominated allyl group.

**Actions and Uses.**—The actions and uses of pernoston are essentially similar to those of barbital, but pernoston is more active than barbital and is used in correspondingly smaller doses. It is promptly absorbed and is rapidly changed and destroyed within the body. It is used in combating insomnia due to emotional strain and nervous instability. In therapeutic doses it is said to produce no demonstrable toxic effects on the heart, lungs, blood vessels and kidneys; it does not interfere with the physiologic activities of these organs.

**Dosage:** One tablet (3 grains) given one-half hour before sleep is desired, preferably followed by a glass of warm milk or lemonade. For hypnosis in the presence of pain: one tablet given in conjunction with aminopyrine or acetylsalicylic acid.

Manufactured by J. D. Riedel-E. de Haen, A. G. Berlin, Germany (Riedel-de Haen, Inc., New York, distributor). U. S. Patent 1,739,662 (December 17, 1929, expires 1946). U. S. trademark 266,216.

*Pernoston Tablets, 3 grains.*

Pernoston occurs as a fine, white, crystalline powder, with a slightly bitter taste; completely soluble in alcohol and ether; very slightly soluble in cold water; insoluble in the paraffin hydrocarbons. A saturated aqueous solution is acid to litmus paper. Pernoston melts at 130 to 133 C.

Place approximately 1 Gm. of Pernoston in a 25 cc. glass stoppered cylinder, add 10 cc. of water and 1 cc. sodium hydroxide solution and shake for one minute, filter through paper and divide into two portions; to one portion add 1 cc. of mercury bichloride solution: a white precipitate results, soluble in 10 cc. of ammonia water; to the other portion add 5 cc. of silver nitrate solution: a white precipitate results, soluble in 5 cc. of ammonia water.

Fuse about 0.1 Gm. of pernoston and 1 Gm. of crushed potassium hydroxide, previously moistened with 1 cc. of alcoholic potassium hydroxide solution, in a nickel crucible: it is decomposed with the evolution of ammonia; cool, dissolve the residue in 10 cc. of water, add 10 cc. of diluted nitric acid, filter through paper; to the filtrate add 5 cc. of silver nitrate solution: a curdy dirty white precipitate results, soluble in excess of stronger ammonia water.

Dissolve 0.1 Gm. of pernoston in 1 cc. of sulfuric acid; the liquid assumes a yellow color, changing slowly to a brownish red, finally to a dark red. Place 1 Gm. of pernoston in a 25 cc. glass stoppered cylinder, add 10 cc. of water, shake for one minute, filter through paper and divide into two portions; to one portion add 0.5 cc. of a saturated bromine water; an immediate decoloration occurs, to the other portion add 0.1 cc. of tenth-normal potassium permanganate: a yellow color appears immediately.

Put 0.5 Gm. of pernoston with 50 cc. of water for two minutes; no color develops; cool and filter; separate portions of 10 cc. each of the

filtrate yield no opalescence with 1 cc. of diluted nitric acid and 1 cc. of silver nitrate solution (chloride); no turbidity with 1 cc. of diluted nitric acid and 1 cc. of barium nitrate solution (sulfate); no coloration or precipitation on saturation with hydrogen sulfide (sulfide and metals).

Incinerate about 1 Gm. of pernoston, accurately weighed; the residue does not exceed 0.1 per cent. Transfer about 0.25 Gm. of pernoston, accurately weighed, to a bomb tube; determine the bromine content by the Carius method: the amount of bromine found should be not less than 26.1 per cent nor more than 26.6 per cent. Dissolve about 0.1 Gm. of pernoston, accurately weighed, in 25 cc. of previously neutralized alcohol; dilute with an equal volume of water and titrate with tenth-normal sodium hydroxide solution, using thymolphthalein as indicator; the amount of tenth-normal sodium hydroxide solution consumed corresponds to not less than 98.5 per cent nor more than 100 per cent of sec. butyl-bromallyl barbituric acid.

### SODIUM GOLD THIOSULFATE (See New and Nonofficial Remedies, 1936, p. 223).

**Gold Sodium Thiosulfate-Merck.**—A brand of sodium gold thiosulfate-N. N. R.

Manufactured by Merck & Co., Inc., Rahway, N. J. No U. S. patent or trademark.

*Ampuls Gold Sodium Thiosulfate-Merck, 0.01 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.025 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.05 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.10 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.20 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.25 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.30 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 0.50 Gm.*

*Ampuls Gold Sodium Thiosulfate-Merck, 1.0 Gm.*

### PENTOBARBITAL SODIUM-LILLY (See New and Nonofficial Remedies, 1936, p. 109).

The following dosage form has been accepted:

*Ampoules Pentobarbital Sodium-Lilly, 0.5 Gm. (7½ grains):* Each ampule contains the stated amount of pentobarbital sodium and is accompanied by a 10 cc. size ampule of distilled water.

## Council on Foods

### THE PRESENT STATUS OF VITAMIN D MILK

FOR MANY MONTHS THE COUNCIL HAS STUDIED THE PROBLEM PRESENTED BY VITAMIN D MILK. IN JUNE 1936 PUBLICATION OF AN EXTENSIVE REVIEW OF THE LITERATURE BY DR. PHILIP C. JENKS (THE JOURNAL, JUNE 13, 1936, P. 2066, AND JUNE 20, 1936, P. 2150) ON THE PRESENT STATUS OF VITAMIN D MILK WAS AUTHORIZED. SINCE THAT TIME THE COUNCIL HAS CONTINUED TO DEVOTE SPECIAL CONSIDERATION TO THE ENTIRE PROBLEM AND, IN THE LIGHT OF KNOWLEDGE AVAILABLE AT THE PRESENT TIME, HAS ADOPTED AND AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT, WHICH WILL SERVE AS A STATEMENT OF THE COUNCIL'S POLICY IN ACCEPTING VITAMIN D MILKS.

FRANKLIN C. BING, Secretary.

The development in our knowledge of vitamin D has been rapid since 1922, when it was shown that the antirachitic factor differed from vitamin A. Now it is known that there are several substances which have a vitamin D effect. The relative lack of this factor in most common foods has become evident. A few foods contain vitamin D in fair amounts, but generally speaking the vitamin is ordinarily obtained by direct irradiation of the skin with sunshine or with certain forms of lamps which furnish the requisite wavelengths, or by the inclusion of substances such as fish liver oils and viosterol in oil, or by foods which have been suitably fortified.

The Council on Foods is particularly concerned with the fortification of foods with vitamin D. In order that fortified products may receive acceptance, a general need for the contemplated addition must be evident and the food to which the addition is made must be a suitable medium.

There is, of course, abundant evidence that infants and very young children need extra vitamin D. Though an increasing proportion of infants receive additional vitamin D in some form, many still do not. Many physicians prefer to prescribe pharmaceutical preparations of vitamin D because of the freedom thus afforded to adjust the dosage to the individual patient. The Council on Foods respects this attitude but at the same time recognizes that a considerable portion of the population unfortunately does not consult a physician except for emergencies. Consequently it seems to the Council to be in the interest of the public as a whole to recognize and accept the fortification of food with vitamin D.

development of a special reflex camera by Henning<sup>22</sup> have notably advanced the technic of endoscopic photography.

A seemingly practical intragastric camera has been developed in the Gastro-Photor camera.<sup>23</sup> This instrument consists of a tubular camera, seven-sixteenths inch in diameter and 2 inches in length, attached to a stomach tube and passed into the stomach after the fashion of an Ewald tube. Sixteen tiny pictures covering the entire circumference of the stomach at two levels are obtained in one exposure of  $\frac{1}{120}$  second. The exposure is automatically controlled by a lamp within the camera, which produces an intense brief blue-white light of about 20,000 candle power. In this manner photographs of ulcers, early carcinomas, polypi and inflammatory changes of the mucous membrane may sometimes be obtained before gastric deformities are discernible by x-ray examination.

#### COLOR PHOTOGRAPHY

*Color Transparencies.*—With scarcely more effort than is required for the making of ordinary black and white photographs, transparencies in full natural color may be made for viewing by hand or in a stereoscope or for lantern projection. Because of the complex nature of the materials used the process is a rather expensive one, and until color materials become less costly monochromatic photography will perhaps remain in general favor.

There are available for color transparencies Agfa, Finlay and Lumière Autochrome plates, and Dufaycolor cut film, roll and 35 mm. motion picture film. Correct exposure in color photography is important, since the latitude of the emulsions is relatively small. A photoelectric exposure meter is therefore a good investment if photography under varying conditions is contemplated. The picture may be taken by daylight, Photoflood or Photoflash light. The exposed plate or film is developed in the usual manner and then reversed and redeveloped. In developing and reversing, strict observance of the formulas and instructions which come with the materials is essential.

Exposure is considerably longer for color than for ordinary emulsions. This means that in most instances time exposures will be necessary. However, snapshots may be made with Photoflash bulbs. Thus, with Agfa color plates and one Photoflash lamp at 3 or 4 feet from the subject, a picture may be taken with stop  $f/6.3$ . With two Photoflood bulbs in reflectors 4 feet from the subject with an opening of  $f/4.5$ , an exposure of from three to five seconds is required. Dufaycolor film, available in standard sizes for roll film and miniature cameras, is considerably faster than most other color emulsions, and snapshots can be made with proper Photoflood illumination. Special filters supplied by the maker of the materials used must be employed.

*Colored Positive Prints.*—Unlike the making of color transparencies, the making of color prints on paper is an extremely tedious process requiring infinite pains and meticulous handling at every stage. Briefly, the process consists of taking three pictures of the subject on a panchromatic film, each picture being made through a different filter—red, green and blue. Exposure must be calculated on the basis of the factor of the filter and emulsion used. The negatives are developed in the usual

manner and three positives made, one on paper and two on transparent film. The positives are next toned in colors complementary to the filter used. The toned print and transparencies are then cemented together with images in superposition.

In the Carbro method, bromide enlargements are made from each of the three separate negatives and used for the production of a pigment print, special blue, magenta and yellow tissues being used. The images are then superimposed in register on paper.

A method that for simplicity promises to replace other color processes is the new Defender Chromatone process. This requires the usual two or three color separation negatives, positive prints of which are made on special gelatin-collodion stripping films, which are toned in the three complementary colors and placed in register on a white background.<sup>24</sup>

The Eastman wash-off-relief film and the set of dyes also afford a convenient method of making color prints from three separation negatives.

Since three separate exposures are necessary for the positive color prints, the choice of clinical subjects is limited. Repeating backs for plate cameras and automatic movement of the film as is obtained in some miniature cameras simplify the process somewhat. There are available also cameras which, by means of mirrors or prisms, allow the simultaneous making of the three separation negatives. These cameras are extremely bulky and expensive. The ordinary roll film or plate cameras require many seconds for the taking of a picture, and therefore average subjects do not lend themselves to the making of satisfactory color positives.

In order to simplify the making of separation negatives, a bipack such as Defender Dupac cut film, which allows two color separation negatives at a single exposure, may be employed. Color prints by this method are not nearly so faithful to the original subject as three color separation negatives. However, with suitable two-color subjects, such as stained specimens in photomicrography, the method can be advantageously used.

#### CLINICAL CINEMATOGRAPHY

Motion pictures of pathologic lesions, modes of treatment and operative procedure constitute a method of teaching that is unparalleled. The perfection of the 16 mm. movie camera has reduced the cost of operation considerably, and the simplification of the apparatus has made movie making as easy as the making of "still" pictures. While the technical quality of 35 mm. motion pictures has not been equaled by the smaller films, the 16 mm. camera has virtues of its own that adapt it to clinical use.

Photoflood bulbs and supersensitive panchromatic emulsions make possible the taking of motion pictures in the operating room, clinic or office. The technic employed is practically the same as that used in making home movies. Pictures in natural color may be made with Kodachrome film<sup>25</sup> and add to realism in filming autopsies, operations, microscopic sections, skin diseases, ophthalmologic diseases and sundry other subjects. A further refinement is an attachment for making talking pictures which permits explanation of the pathologic lesions or operative methods on the screen.

24. Full details of this process are described in a booklet supplied at the price of 25 cents by the Defender Photo Supply Company, Inc., Rochester, N. Y.

# THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - - CHICAGO, ILL.

Cable Address - - - "Medic, Chicago"

Subscription price - - - - Seven dollars per annum in advance

*Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.*

SATURDAY, JANUARY 16, 1937

## ANNUAL DUES NOW PAYABLE

The colored slip inserted in this issue of *THE JOURNAL* is a reminder that the annual subscription and Fellowship dues for the current year are payable in advance. When properly folded the slip forms a convenient, safe, postage-prepaid envelop for carrying a check, draft or money order. With *THE JOURNAL* are listed the eight special journals published by the American Medical Association, and also *Hygeia*, the Health Magazine, with the respective subscription prices. This makes it convenient to subscribe for other publications in addition to *THE JOURNAL*, since all may be covered with the one order and remittance. The thousands of subscribers who have already paid the 1937 dues will of course disregard the colored slip.

## REORGANIZATION OF GOVERNMENTAL MEDICAL ACTIVITIES

At a special session of the Board of Trustees in the headquarters office last week consideration was given to the proposed reorganization of governmental activities, and particularly to the changes likely to be recommended in the consolidation of those affairs of the government which concern preventive medicine and medical service. For some years the proposal to reorganize these affairs with a view to efficiency, economy and more successful administration has been advanced by various presidents, cabinet officers and members of governmental legislative bodies. At present, the whole question is being studied by committees of the Senate and of the House of Representatives and, in addition, by a special committee appointed by the President to advise him personally.

Following extended consideration of the problem of reorganization of governmental medical activities, the Board of Trustees adopted the following resolution,

which was forwarded immediately to the members of the various committees that have been mentioned:

"Recognizing that committees of the Senate and of the House of Representatives of the United States government and a special committee appointed by the President are at this time concerning themselves with the reorganization of government activities with a view to greater efficiency and economy, and recognizing also that the President, in his opening address to Congress, indicated that he would shortly present to the Congress recommendations for such reorganization of governmental activities in the executive branches, and recognizing moreover the great desirability that all activities of the federal government having to do with the promotion of health and the prevention of disease might with advantage be consolidated in one department and under one head, the Board of Trustees of the American Medical Association would recommend that such health activities as now exist be so consolidated in a single department which would not, however, be subservient to any charitable, conservatory or other governmental interest. It has been repeatedly said that public health work is the first problem of the state. It is the opinion of the Board of Trustees that health activities of the government, except those concerned with the military establishments, should not be subservient to any other departmental interests. This reorganization and consolidation of medical departments need not, under present circumstances, involve any expansion or extension of governmental health activities but should serve actually to consolidate and thus to eliminate such duplications as exist. It is also the view of the Board of Trustees that the supervision and direction of such medical or health department should be in the hands of a competently trained physician, experienced in executive administration."

Press reports indicate that the President proposes to send his message on the subject to Congress during the week in which this issue of *THE JOURNAL* appears. No doubt, by the time this editorial becomes available to our readers the matter will already be under consideration by the Senate and the House of Representatives. The views presented by the Board of Trustees are presented with due regard for the scientific and medical interests involved and particularly with the idea of conserving in governmental medical affairs the fundamental principles which the House of Delegates has established as necessary to the best interests of the public in general, and particularly of the person who is ill, whether or not he is a ward of the government or a patient seeking relief at the hands of a private physician. The experience of many hundreds of years in the practice of medicine has shown how important

vated charcoal has been recommended on the ground that it has a higher adsorptive capacity. This is merely charcoal that has been heated to a certain temperature. Because charcoal has a strong affinity for gases, it should be kept tightly stoppered to prevent its deterioration and from becoming impregnated with unpleasant odors.

Kaolin is a clay that has been used for centuries in China<sup>7</sup> for summer diarrheas, as well as for cholera, and was first heard of in Europe during the eighteenth century.<sup>8</sup> Father Deutrecolle, a Jesuit missionary, described in 1712 the clay works in China and mentioned that the clay was used in treating diarrhea. It is now obtained from different parts of Europe and the United States. Kaolin is a mixture of aluminum silicate and other substances but has a somewhat different composition, depending on the area from which it is obtained and how it has been treated. According to Fantus,<sup>2</sup> the three most commonly used preparations of aluminum silicate have the analyses given in the accompanying table.

*Analysis of Silicon Dioxide, Aluminum Oxide, Ferric Oxide and Calcium Oxide*

	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	Fe <sub>2</sub> O <sub>3</sub>	CaO
Kaolin .....	45.4	1.92	1.92	0.44
Fullers' earth .....	57.26	18.33	1.87	2.58
Lloyd's reagent .....	55.30	9.82	14.80	1.58

Several reports speak highly of the value of kaolin in the treatment of Asiatic cholera. Braafladt<sup>8</sup> reports that Kuline, with the use of kaolin, together with hypertonic salt solution reduced the mortality from cholera among the soldiers in the Balkan war of 1910 from 60 per cent to 3 per cent. McRobert<sup>9</sup> advocates kaolin in treating the acute bacterial food poisonings which he encountered in the British army in India. Hess,<sup>10</sup> on the other hand, found kaolin to be of little value in the treatment of intestinal disorders of infants; whereas, fullers' earth gave considerable satisfaction. He suggests that the difference in effectiveness may come from the greater amount of calcium contained in fullers' earth. If his suggestion is correct, it is probable that he was dealing with dietary disturbances rather than infections. Studies in vitro suggest that the beneficial action of kaolin depends on the adsorption of the cholera toxin and inclusion of the bacteria. Others have expressed the belief that the effect of kaolin in diarrhea is the removal of colloids from the intestinal fluid, thus decreasing its osmotic pressure and allowing more rapid absorption of this fluid by the intestine. How little is known about what really transpires is illustrated best by the common experience with barium sulfate. Every physician has had the opportunity of seeing patients who are severely constipated by barium sulfate given for roentgenographic studies, whereas others develop a temporary diarrhea. Yet no one can predict what effect barium sulfate is going to have on a particular individual.

Fantus<sup>2</sup> has shown that kaolin exerts other effects. It has a strong affinity for alkaloids in an acid medium

but loses this attraction in an alkaline medium. It changes the intestinal flora from a proteolytic to an aciduric one over a period of from ten to thirty days.<sup>9</sup> The attempt to explain this effect by the suggestion that it removes proteolytic products of digestion seems questionable. Kaolin adsorbs materials that act as acids, but not alkalis, and the products of protein digestion behave as alkalis.

In addition to the use of charcoal and kaolin, there are other adsorbents which would repay further study, especially barium sulfate and aluminum hydroxide. The latter, a particularly good adsorbent, has the advantage of being an amphoteric substance (that is, can act as an acid or an alkali) and can be produced in the form of a gel. Rakusin<sup>11</sup> suggests that it might be used to advantage in intestinal infections.

#### LIMITATIONS AND POSSIBLE DANGERS IN THE USE OF ADSORBENTS

Before prescribing adsorbents, one should keep in mind certain facts that limit their usefulness. One is the quality already mentioned of acting as an acid or an alkali, or an amphoteric substance. Because the reaction of the intestinal tract varies from the stomach to the rectum, one cannot predict results on a priori reasoning or test tube experiments. Moreover, an adsorbent may have an irreversible affinity for one substance and an easily reversible reaction with another, factors that will influence their use in the intestinal tract.

Because adsorbents are porous and are supposed to act by the removal of undesirable products, large quantities are necessary if one is attempting to nullify the effect of such things as toxins, bacteria, or gases which are constantly being replenished. However, large doses may cause undesirable effects by removing elements such as vitamins, enzymes or essential minerals. Messerli<sup>12</sup> has shown that rats and pigeons fed on a diet of decorticated rice developed an avitaminosis more rapidly and more severely if blood charcoal or bolus alba (kaolin) was mixed in the diet. Deobald and Elvehjem<sup>13</sup> found that if soluble iron and aluminum salts were fed to day-old chicks in large amounts the birds developed severe rickets in from one to two weeks. A definite drop in the blood phosphorus was observed as early as the fifth day. In addition to such effects, the chance of producing undesirable constipation must be remembered. Because many therapeutic adsorbents are products of clay they have a tendency to settle and plug small openings, with resulting danger to the patient with a partial intestinal obstruction. A partial obstruction may be converted quickly to a complete one by the injudicious use of these substances. Because of the completeness with which these preparations lose water, hard concretions may form, causing serious trauma to the colon or even perforation. Long, Kolmer and Swalin<sup>14</sup> report that Hoelzel has produced polyposis in the rat's intestine by incorporating kaolin in the diet in the proportion of two to one, but after repeating Hoelzel's work they believe that this outcome

indigent are being given a high quality of medical care and medical service. Nevertheless, the advances of medical science have created situations in which a group of the population neither wholly indigent nor competent financially find themselves under some circumstances unable to meet the costs of unusual medical procedures. The Board of Trustees of the American Medical Association points out the willingness of the medical profession to do its utmost today, as in the past, to provide adequate medical service for all those unable to pay either in whole or in part. Members of the medical profession, locally and in the various states, are ready and willing to consider with other agencies ways and means of meeting the problems of providing medical service and diagnostic laboratory facilities for all requiring such service and not able to meet the full cost thereof. These are problems for local and state consideration primarily rather than problems of federal responsibility. The willingness of the medical profession to adjust its services so as to provide adequate medical care for all the people does not constitute in any sense of the word an endorsement of health insurance, either voluntary or compulsory, as a means of meeting the situation."

#### CLIMATE AND RHEUMATIC FEVER

The relative incidence of rheumatic fever in certain well defined regions of the United States has been a subject for study for many years. As long ago as 1924 Faulkner and White<sup>1</sup> observed that the incidence of rheumatic fever was much lower in the southern than in the northern part of the United States. Other investigators have since then arrived at the same conclusion. Recently Nichol<sup>2</sup> reported the results of observations at a hospital of more than 300 beds in Miami, Fla., over the five year period that ended with 1934. In the five years he observed only eleven cases of rheumatic fever or carditis and no cases of chorea among 8,287 medical admissions to the hospital, including children. During the same period at a large hospital in Boston Dr. S. A. Levine observed 137 cases of rheumatic fever, carditis or chorea among 9,817 medical admissions. The relative incidence of rheumatic fever among the admissions in these two hospitals (one in Miami and the other in Boston) was respectively 0.13 and 1.4 per cent. In his report Nichol tabulates the medical admission rate of rheumatic fever or chorea previously reported by investigators in various sections of the United States. Generally this tabulation indicates that the admission rate in certain hospitals in the southern part of the United States is less than it is for certain hospitals in the northern part. After allowances are made for some factors that might detract from the reliability of comparing statistics of this kind, it still seems that clinically perceptible rheumatic fever and rheumatic heart disease are much less common in southern than in northern regions of the United States. In office practice during

the four years that ended with 1934 Nichol classified sixty-eight cardiac cases as having a rheumatic etiology; however, all but one of these patients had acquired rheumatic disease before leaving the North and in only one instance in this group was there clinical evidence of reactivation of a presumably healed rheumatic carditis during their stay in the South. The actual rareness of rheumatic fever in the South has been questioned by some writers. Nichol, however, who has practiced in southern Florida for ten years, is convinced that even the mild or smoldering form of carditis is uncommon while the obvious cases with arthritis or chorea are rare. In the discussion of this paper, Dr. John R. Mote of Boston again pointed out that hospital records may not always indicate the real incidence of a disease and that certain discrepancies appear in reports from all over the world on the occurrence of rheumatic fever which require verification. Mote also said that a small group of children with rheumatic fever had been sent each year from Boston to Miami Beach to evaluate if possible the effect of a subtropical climate on the course of the disease. In four years, twenty-three children in all were sent. In general these young patients did better and recrudescences were shorter than in the North, although exacerbations of the rheumatic fever did occur in some of these patients while they were in Florida. Levine of Boston further stated that in a 200 bed hospital in ten years there will be some patients dying of rheumatic mitral stenosis which will be recognized as such by the pathologist at necropsy. Levine had observed that the incidence of mitral stenosis at the Charity Hospital in New Orleans was one twentieth of what it was at the Peter Bent Brigham Hospital in Boston. Nichol added the observation that 1,500 school children born and reared in Miami had been compared with 1,500 school children who had migrated to Miami. The incidence of rheumatic heart disease was found to be four times greater in the migrated group than in the native group. While the reports of some other writers tabulated by Nichol indicate a relatively lower incidence of rheumatic fever among hospital admissions in the southern part of the United States, the data available do not appear to be sufficient for a nation-wide comparison.

#### THE POSSIBILITY OF HUMAN SELENIUM POISONING

The occurrence of selenium poisoning, or "alkali disease," in live stock and in human beings in the state of the North Central Great Plains has frequently been mentioned editorially in THE JOURNAL.<sup>1</sup> Now Smith, Franke and Westfall<sup>2</sup> have studied 111 families living on farms and ranches in Wyoming, South Dakota and Nebraska. Though no serious illness was observed that resembled natural or experimental selenium poisoning, a large proportion of the subjects examined showed fad teeth varying from marked discoloration to decay, and or intense icterus suggesting liver damage, various types of skin eruptions, rheumatoid and deforming forms of arthritis, disease of the finger nails with transverse ridges

**Autointoxication.**—Several observers have reported that the continued use of kaolin will result in a change of the intestinal flora from a proteolytic to an aciduric one, entirely analogous to what is observed after the feeding of lactose. The change is explained on the theory that the kaolin removes the proteolytic products of digestion, thus allowing the aciduric organism to outgrow the others. As a result of such studies the suggestion is made occasionally that adsorbents are indicated in the treatment of so-called autointoxication. But, because the mechanism of autointoxication is not yet known and because many do not believe that such a condition exists, the use of adsorbents for this purpose is not warranted in our present state of knowledge.

#### SUMMARY

Charcoal and kaolin have been given for their effect on the gastro-intestinal tract for many years. During this time a limited number of clinical reports have expressed their value in the treatment of diarrhea and the alleviation of dyspeptic symptoms. Renewed interest in their use has developed largely because of their adsorbent qualities. Laboratory studies confirm their possible usefulness but also demonstrate the number of complicating reactions that may occur in the gastro-intestinal tract. Further, carefully controlled investigations are needed in the clinic and laboratory before therapy with these substances can be regarded to be on a sound foundation.

319 Longwood Avenue.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

### HOLMSPRAY ATOMIZERS NOS. 540 AND 595 ACCEPTABLE

Manufacturer: T. J. Holmes Company, Inc., Chertley, Mass. The firm's description of these atomizers follows:

**Nasal Atomizer No. 540.**—A nose and throat atomizer for alcoholic aqueous and oily solutions. Vacuum type construction. Extra cap included for sealing filled bottle. Nickel plated metal parts. Plain rubber bulb. Fitted to a ½ ounce prescription bottle.

**Throat and Nasal Atomizer No. 595.**—An atomizer designed for spraying ephedrine solutions, and for oily solutions when the application has to be made in small volume. It produces a very fine and fluffy spray. Heavy quality nickel plated metal parts, adjustable spray nozzle, glass liquid tube, 1 drachm capacity amber colored bottle.

The investigator for the Council to whom these atomizers were referred for trial reported them as satisfactory. In view of the favorable report, the Council on Physical Therapy voted to include the Holmspray Atomizers Nos. 540 and 595 in its list of accepted devices.

Holmspray Atomizer.

#### CORRECTION

In the report "Eveready Two-Bed Carbon Arc Lamp, Model A-22, Acceptable," published in *THE JOURNAL*, Nov. 7, 1936, page 1561, a transposition of figures recorded the efficiency of the transformer at 49 per cent. The efficiency of the transformer should have read 94 per cent.

## Council on Pharmacy and Chemistry

### REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. PAUL NICHOLAS LEECH, Secretary.

### CARASYL PLAIN, CARASYL WITH CASCARA, and CARASYL WITH ALOIN AND CASCARA NOT ACCEPTABLE FOR N. N. R.

Carasyl Plain, Carasyl with Cascara and Carasyl with Aloin and Cascara were presented for Council consideration by the Lorayne Laboratories. They are proposed for use in the treatment of colitis and chronic constipation. Carasyl is stated to be composed of psyllium flour, karaya gum and fig flour, the fibers and seeds of figs, and fiber of psyllium seed having been removed. Carasyl with Cascara is stated to differ from the plain by the addition of one-half grain of "powdered debitterized extract of cascara" to each 60 grains of the plain Carasyl. The Carasyl with Aloin and Cascara is stated to contain one-fifth grain of cascara (presumably the same extract as that in the Carasyl with Cascara) and one-fortieth grain of aloin to each 60 grains of the product. In all cases each drachm is declared to contain 4 minims of liquid petrolatum, which is added to prevent caking.

The average dose of the official extract of cascara is 0.3 Gm. (5 grains). If the "debitterized" extract is of the same activity as the official, a dose of Carasyl with Cascara contains about one-eighth the average dose; and the Carasyl with Cascara and Aloin contains about one-twentieth of the average dose of the extract of cascara, and about one-eighth of the average dose of aloin given by the U. S. P. As a matter of fact the average dose of aloin is more than that given by the U. S. P., 0.015 Gm. (one-fourth grain); the British Pharmacopoeia gives from one-fourth to 1 grain (Imperial).

The advertising submitted by the firm states that the cascara in such a small dose acts as a mild bowel tonic. It is stated that this product fortified with aloin is for patients with very pronounced atonicity of the colon.

It is stated in the advertising that Carasyl is a scientifically prepared bowel normalizer; that obese patients on a limited diet do well to take a small dose at the beginning of each meal in a glass of hot skimmed milk. It is claimed that this is quite satisfying to the appetite, regulates the bowels and takes the place of more fattening food. It is stated that when prepared according to approved directions it is pleasant and agreeable to take and may be used indefinitely with continuing beneficial results.

No evidence is presented to show that this mixture of psyllium flour, karaya gum and fig flour (no therapeutic claim is made for the liquid petrolatum) is therapeutically superior to an equal weight of psyllium flour alone; nor is any satisfactory evidence presented to show the therapeutic advantage of combining the mixture with such small amounts of cascara or aloin or with both of them. It is not in the interest of therapeutic practice to give the approval of the Council to such mixtures, in the absence of any satisfactory evidence that they have any therapeutic advantage over the simple psyllium flour. It is better to give aloin and cascara when they are specifically indicated, and then in doses that may be expected to produce definite effects.

The name Carasyl is objectionable as being a proprietary designation for an unoriginal mixture of well known ingredients.

In the Council's consideration of the Carasyl products, attention was called to the paper of MacKay, Hall and Smith, "Renal Pigmentation Following Ingestion of Psyllium Seed" (*Proc. Soc. Exper. Biol. & Med.* 30:152 [Nov.] 1932).

These authors reported that, when ground psyllium seed is fed as an addition for roughage to rats or to dogs, there is darkening of the kidneys, and after long continued feeding pigment granules are visible microscopically in the tubules of rats. The feeding of whole psyllium seed does not produce the pigmentation. Although the authors do not prove that any injury was caused, the Council held that it is not improbable

auspices of the Chemical Foundation, Inc., and was author of the book on Qualitative Analysis which revolutionized the teaching of this subject. He was president of the American Chemical Society in 1917 and received the Willard Gibbs Medal of its Chicago section in 1923. Throughout his entire teaching period he maintained an active interest in the humanitarian side as applied to medicine, which was widely recognized and appreciated by organizations representing progressive medicine.

### INDIANA

**Secretaries' Annual Conference.**—The Indiana State Medical Association will hold its secretaries' annual conference at the Columbia Club, Indianapolis, January 31. The Rural Resettlement Administration will be discussed by Dr. Houston W. Shaw, Henryville; Dr. Neal Matlock, Medora; M. E. Hays, Indianapolis; Dr. Ralph C. Williams, Washington, D. C., national medical director of the administration, and Dr. Verne K. Harvey, Indianapolis, director of the Indiana Division of Public Health. Other speakers will include:

Dr. James B. Maple, Sullivan, Present Trends in County Medical Society Programs.

Albert Stump, Indianapolis, attorney for the state association, Discussion of Joint Meetings with Professional Groups.

Dr. Eldridge M. Shanklin, Hammond, The Journal of the Indiana State Medical Association.

Dr. Norman M. Beatty, Indianapolis, The Legislative Outlook.

Thomas A. Hendricks, executive secretary, Indiana State Medical Association, The County Medical Society and the Headquarters Office.

There will be a round table discussion of local medical society problems. At the banquet in the evening, Dr. Herman M. Baker, Evansville, president-elect of the state society, will be introduced, and Dr. Charles Gordon Heyd, New York, President, American Medical Association, will discuss "The Service of the American Medical Association to Society."

### KENTUCKY

**Bill Introduced.**—S. 16-XXXX proposes, among other things, to liberalize those provisions of the workmen's compensation act requiring an employer to furnish medical, surgical, hospital and nursing service to an injured employee. This bill proposes (1) to increase the normal limit of an employer's liability for medical, surgical and hospital treatment from \$100 to \$200 and (2) to authorize the compensation board to direct in a particular case an extension of this limit of expense to not exceeding \$400. If the charges made by hospitals and physicians in a particular case exceed the aggregate charges for which an employer is liable, the board is to be authorized to apportion payments to the respective parties.

### MARYLAND

**Dr. Eagle Wins Lilly Award.**—The \$1,000 prize and bronze medal of Eli Lilly and Company, Indianapolis, was presented at the annual meeting of the Society of American Bacteriologists in Indianapolis, December 29, to Dr. Harry Eagle, Baltimore, for accomplishments in research on immunity to various diseases, notably syphilis, it is announced. A committee composed of members of the Society of American Bacteriologists, the American Association of Immunologists and the American Society for Experimental Pathology selected Dr. Eagle, whose research has been done largely in the medical schools of Johns Hopkins University and the University of Pennsylvania. Dr. Eagle is 31 years of age and graduated from Johns Hopkins University School of Medicine in 1927. He is a passed assistant surgeon general of the U. S. Public Health Service and a member of several scientific societies. Before coming to Johns Hopkins Hospital, where he is now stationed, Dr. Eagle was assistant professor of bacteriology at the University of Pennsylvania School of Medicine.

### MICHIGAN

**The Beaumont Lectures.**—Elmer V. McCollum, Sc.D., professor and head of the department of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, will deliver the annual Beaumont Lectures of the Wayne County Medical Society, February 15-16, on "Recent Advances in the Field of Nutritional Research." The tentative titles of the individual lectures are "Recent Advances in Our Knowledge of the Vitamins" and "Present Status of Nutritional Problems Involving Inorganic Elements."

**"Traffic Clinic" to Reduce Accidents.**—The New York Times describes a "traffic clinic" recently inaugurated in Detroit to reduce automobile accidents. Of the first 100 cases examined in the clinic after its opening in October, fourteen persons were found too seriously crippled to drive, seven insane and ten feebleminded. The tests include an intelligence test,

a physical examination centered on the heart, eyes and reflex actions, and a personal interview with the psychiatrist. The objective of the clinic is not merely to eliminate faulty drivers but to put good drivers on the streets, since, it was pointed out, many of the defective drivers can correct their faults by education, glasses or medical treatment. Dr. Lowell S. Selling is the psychiatrist in charge of the new traffic unit.

**Campaign Against Tuberculosis.**—The city council of Detroit has made available \$105,000 for six months beginning January 1 to assist in a campaign against tuberculosis, according to the *Detroit Medical News*. The campaign was recently launched under the efforts of the Wayne County Medical Society, the Detroit Tuberculosis Sanatorium Association, the *Detroit News*, Radio Station WWJ, the Detroit Department of Health, and Paul de Kruif. To carry out the program, three full time physicians, forty-five nurses and ten clerks have been added to the city health department; in addition, 700 physicians have agreed to cooperate. Since December 3, 399 patients have been tuberculin tested, 100 of whom gave positive reactions. In sixty of those having positive tests x-ray examination showed that twelve have active tuberculosis, ten have the disease in the healed or quiescent form, three were reported as needing further examination, and thirty-seven gave no evidence of the disease. Five of the twelve active cases were in the incipient stage.

### MINNESOTA

**Personal.**—Dr. Adolph M. Hanson, Faribault, has been named an associate in research of the Philadelphia Institute for Medical Research; he will continue his research on the thymus and pineal glands in his laboratories at Faribault.—Dr. Byrl R. Kirklin, Rochester, Minn., has been appointed a corresponding member of the German Society of Roentgenologists.

**Annual Judd Lecture.**—Dr. Evarts A. Graham, Bixby professor of surgery, Washington University School of Medicine, St. Louis, will deliver the fourth annual lecture in the E. Starr Judd Lectureship in Surgery, February 3, in the chemistry auditorium of the University of Minnesota, Minneapolis. His subject will be "Accomplishments of Thoracic Surgery and Its Present Problems." The lectureship was established at the university by the late Dr. Edward Starr Judd, Rochester.

**Study of Medical Costs.**—At a recent meeting of the council of the Minnesota State Medical Association, a committee was named to investigate the possible sources of financial aid for a study of medical costs in the state. Members of the committee are Drs. Alfred W. Adson, Rochester, president of the association; William W. Will, Bertha, and Edward A. Meyerding, St. Paul. The study would cover the cost to the student and the state of a medical education, the cost to the practicing physician of overhead, equipment, transportation, expert assistance, and the relation of physicians to population groups and related problems.

**Dr. Taylor to Direct Research for General Mills.**—Dr. Alonzo E. Taylor, director of the Food Research Institute at Stanford University, Calif., since 1921, has been appointed chairman of the research committee of General Mills, Inc., Minneapolis, to have general direction of the firm's research in diet and nutrition. Dr. Taylor, a native of Iowa, graduated from the University of Pennsylvania School of Medicine in 1894. He was professor of pathology at the University of California from 1899 to 1910 and went from there to the University of Pennsylvania, where he was first professor of physiology and then Benjamin Rush professor of physiological chemistry until 1921. During the World War he investigated food conditions in Europe for the federal government and the U. S. Relief Administration and was a member of the War Trade Board from 1917 to 1919. In 1927 he was a delegate to the International Economic Conference in Geneva and in 1931 served as consulting expert attached to the American delegation to the International Wheat Conference in London. Dr. Taylor's headquarters will be in Minneapolis.

### NEBRASKA

**Dr. Nilsson Appointed Chief Surgeon of Union Pacific.**—Dr. John R. Nilsson, associate professor of surgery, University of Nebraska College of Medicine, has been appointed chief surgeon of the Union Pacific Railroad. He was division surgeon from 1924 to 1928, when he was made chief surgeon of the eastern division. Dr. Nilsson is president of the staff of Immanuel Hospital and is on the staffs of the Methodist and St. Joseph's hospitals, Omaha. He is 58 years old and a graduate of the University of Nebraska College of Medicine.

After two or three years of age, a moderate deprivation of vitamin D rarely has been known to produce illness which leads to medical consultation. The requirements of children and of adults for vitamin D are not accurately known. The assumption that the child needs less than the infant has become widespread. A special need of vitamin D in the food of adults, with the exception of pregnant and lactating women, has not been demonstrated experimentally. Under certain circumstances it would seem that additional vitamin D in the diet of some adults is probably desirable. The Council believes that a moderate amount of vitamin D in addition to that which is normally obtained is a factor of safety in nutrition and health, at least during the period of growth. If the vitamin D addition during childhood and later years is reasonable, e. g., up to four or five hundred units daily,<sup>1</sup> it is believed that possibly some benefit will ensue and certainly no harm.

Of all the common foods available, milk is most suitable as a carrier of added vitamin D. Vitamin D is concerned with the utilization of calcium and phosphorus, of which milk is an excellent source. *The Council has recently made the decision that for the present milk is the only common food which will be considered for acceptance when fortified with vitamin D.*

The properties of vitamin D may be imparted to milk by irradiation of the milk, by proper feeding of vitamin D preparations to cows and by the direct addition to milk of either natural or manufactured vitamin D concentrates. Available evidence indicates that rat unitages of these various products may not have equivalent relative human values. Those products containing vitamin D of so-called animal origin, presumably related to cholesterol, may be more potent than those containing vitamin D of so-called vegetable or plant origin, and produced from ergosterol. From the evidence which has been reviewed by Jeans,<sup>2</sup> in a report to the Council, it appears possible that it may require somewhat more than one unit of vitamin D of plant origin to be equivalent in human value to one unit of vitamin D of animal origin. Thus clinical evidence of the nutritive value of each form of vitamin D milk is necessary in order to evaluate it properly.

Up to Nov. 1, 1936, the Council on Foods has reviewed the evidence and accepted the following types of vitamin D milk:

1. Irradiated fresh (pasteurized) milk (produced under the Steenbock patent) containing 135 units of vitamin D to the quart, and irradiated evaporated milk containing the same number of units to the reconstituted quart (after dilution with an equal volume of water).
2. Fresh (pasteurized) milk containing a concentrate of cod liver oil (Vitex) with 400 units of vitamin D to the quart, and evaporated milk containing the same number of units to the reconstituted quart.
3. Fresh (pasteurized) milk containing 400 units of vitamin D to the quart, the vitamin D being prepared from ergosterol by a process of activation which is fundamentally different from the photochemical process previously described in the scientific literature or descriptions of patents (Sun-A-Sured).
4. Evaporated milk containing a cod liver oil concentrate made by the Clo-Dee (Barthen) process and containing 400 units of vitamin D to each 14½ ounces by weight.
5. Various mixtures designed for infant feeding containing cod liver oil or other sources of vitamin D. Dried milk preparations fortified with vitamin D have also been accepted.

Because of its importance to the public, to physicians and to manufacturers, the Council believes at this time that it would be well to summarize those claims which appear to be well established for vitamin D milks, considering the problem from the point of view both of infant nutrition and of the nutrition of older children and adults.

#### *Vitamin D Milk as a Food During Infancy:*

The vitamin D requirements during the period of most active growth, when rickets may occur, are generally thought to be

greater for each unit of weight than at any other time. It has been shown by controlled feeding tests that irradiated milk containing 135 units to the quart usually will prevent rickets when ingested by normal full term infants in the customary quantities which physicians prescribe. There is evidence, however, that this amount of vitamin D is rather close to the minimum requirements. The evidence indicates also that most infants are better safeguarded when they are given amounts of vitamin D in addition to that furnished by milk containing 135 units to the quart. When milk containing 400 units of vitamin D of so-called animal origin is administered, rickets usually is prevented in normal full term infants if the milk is fed in the customary quantities that are prescribed by physicians.

Though milk with 400 units of animal source vitamin D to the quart may ultimately prove to supply more vitamin D than is sufficient for the need of the average infant, definite knowledge is not at present available.

The evidence concerning the relative effectiveness of vitamin D milk containing vitamin D of so-called vegetable or plant origin is not extensive. However, even though the potency of these milks on a rat unit basis may possibly be less than that of milk containing animal source vitamin D, there appears to be a sufficient margin of safety when the concentration of vitamin D is 400 or more units to the quart. Milks with 400 to 430 units of plant source vitamin D to the quart usually prevent rickets when fed in customary amounts. Probably also they supply an adequate margin of safety and possibly more vitamin D than is sufficient for the need of the average infant, but definite knowledge of these statements is not available at present.

The management of individual variations among infants should remain in the hands of the physician. Physicians who prefer larger quantities of vitamin D than those under discussion can easily prescribe more as a supplement.

#### *Vitamin D Milk as a Food for Children and Older Persons:*

All forms of vitamin D milk which stand accepted by the Council may be said to aid in the proper development of bones and teeth. It is permissible to state, therefore, that vitamin D milks have enhanced nutritive value for children and adults. Indeed, vitamin D milk possibly has a greater usefulness for the child than for the infant because of the larger proportion of children than of infants who do not receive vitamin D from special sources.

#### *Requirements and Allowable Claims for Vitamin D Milk:*

To be acceptable to the Council on Foods, bottle caps and labels for vitamin D milks must declare unitage of the vitamin D in terms of U. S. P. units and the source of the vitamin D, unless local governmental regulations prohibit such declaration.

For all milks containing a minimum of 135 units, an enhanced nutritive value, especially for growing children, may be claimed; it is also permissible to state that these milks usually will prevent clinical rickets when they are fed to normal infants in customary quantities.<sup>3</sup> For milk with only 135 units to the quart there shall be no claim or intimation that an adequate amount of vitamin D is being supplied to infants. When the milk contains as much as 400 units to the quart the claim may be made that the amount of vitamin D is greater than that usually required for the prevention of rickets in normal infants and thus that a margin of safety is offered when customary amounts of milk are taken.

The foregoing statements which have been made concerning vitamin D in fresh milk apply equally to evaporated milk after it has been diluted with an equal volume of water.

In the advertising of vitamin D milk the implication should not be made that the Council favors the use of any vitamin D fortified milk over the prescribing of other forms of vitamin D for infants or recommends the use of vitamin D milk to the exclusion of an additional supply of the vitamin in some other form.

1. Whenever units of vitamin D are mentioned in this report, U. S. P. XI units are meant.

2. Jeans, P. C.: Vitamin D Milk, The Relative Value of Different Varieties of Vitamin D Milk for Infants: A Critical Interpretative Review, J. A. M. A. 106: 2066 (June 13), 2150 (June 20) 1936.

3. For the purpose of this report the expression "customary quantities" may be interpreted to mean from 1½ ounces for each pound of body weight in early infancy and 1½ pints or more daily in later infancy.

## GENERAL

**Exhibition of Scientific Photography.**—An international exhibition of applied and scientific photography is to be held in Rochester, N. Y., in March under the sponsorship of the Rochester section of the Photographic Society of America. C. B. Neblette, Rochester Athenaeum and Mechanics Institute, is secretary and Gustave Fassin, Bausch and Lomb Scientific Bureau, Rochester, chairman, committee on exhibits.

**Prize Awarded for Virus Study.**—Wendell M. Stanley, Ph.D., of the staff of the Rockefeller Institute for Medical Research, New York, received the \$1,000 prize of the American Association for the Advancement of Science at the winter meeting in Atlantic City, January 1, for his contributions to science in the isolation of the virus of tobacco-mosaic disease and studies on the nature of the virus. Dr. Stanley is 32 years old and a native of Indiana. He received the degree of master of science at the University of Illinois in 1927 and doctor of philosophy in 1929. After teaching a year at Illinois he spent two years in study in Munich and in 1931 joined the Rockefeller Institute.

**The Search for Dr. Woodruff.**—Members of the American Medical Association are asked to be on the alert for information or clues that may help in locating Dr. Harry W. Woodruff Jr., who disappeared December 29 from the St. Louis City Hospital.

Harry W. Woodruff Jr., M.D.

It is thought that he may be a victim of amnesia and that he may sooner or later call on a physician for assistance. Dr. Woodruff is 28 years old, is 5 feet 10½ inches tall, and weighs from 155 to 160 pounds. He has a medium dark complexion and there is a slight bald spot on the right side of his head above the hair line. He graduated from Harvard Medical School, Boston, in 1933. Up to January 8 Dr. Woodruff had not communicated with any of his friends, relatives or acquaintances. Any physician who may come into possession of information concerning him is asked to communicate immediately with the St. Louis Police Department, the superintendent of the St. Louis City Hospital or the young man's father, Dr. Harry W. Woodruff Sr., 1201 Western Avenue, Joliet, Ill., telephones 2-2583 (home) and 4455 (office). A reward of \$250 is offered for information concerning his whereabouts.

**Society News.**—Dr. Fred W. Rankin, Lexington, Ky., was elected president of the Southern Surgical Association at its annual meeting at Edgewater Park, Miss., December 15-17. Drs. Charles W. Flynn, Dallas, Texas, and Lucian H. Landry, New Orleans, were elected vice presidents and Dr. Edward William Alton Ochsner, New Orleans, reelected secretary for five years. The 1937 meeting will be held in Birmingham, Ala.—Dr. Isador H. Coriat, Boston, was elected president of the American Psychoanalytic Association at its annual meeting in New York, December 28-29; Dr. Adolph Stern, New York, vice president, and Dr. Lewis B. Hill, Baltimore, secretary.

**Prevalence of Influenza and Pneumonia.**—Newspapers in various parts of the country report that influenza and pneumonia are prevalent. New York papers reported January 10 that 1,571 cases of influenza and 1,120 of pneumonia had been reported during the week ended January 9, compared with 699 and 680, respectively, for the preceding week. There were sixty-nine influenza deaths and 381 pneumonia deaths during the week ended January 9. Influenza was apparently decreasing, as 218 cases of influenza were reported January 9 as compared with 250 the previous day. Pneumonia, however, increased from 148 reported January 8 to 261 reported January 9.—In Chicago it was stated January 8 that 189 deaths had been attributed to influenza and pneumonia since January 1, with about 100 cases a day being reported. Last year only seventy-seven deaths were recorded for the same period from these diseases. During December, 458 deaths were attributed to the two diseases.—At Yale University eighty cases were reported January 11; it was said that the university infirmary was overflowing and attendance at classes was low.—For the week ended January 2 the U. S. Public Health Service reported 3,923 cases as compared with 2,688 in the previous week.

**Medical Bills in Congress.**—*Bills Introduced:* S. 5, introduced by Senator Sheppard, Texas, for Senator Copeland, New York, and H. R. 300, introduced by Representative Chapman, Kentucky, propose to prevent the adulteration, misbranding and false advertising of food, drugs, devices and cosmetics in interstate, foreign and other commerce subject to the jurisdiction of the United States. S. 6, introduced by Senator Lueden, Minnesota, proposes to provide for a nation-wide system of social insurance. A social insurance fund is to be created by an appropriation of \$5,000,000,000, from which compensation is to be paid to unemployed, aged or disabled workers. A worker is to be considered disabled if by reason of a physical or mental condition, sickness or handicap he is rendered incapable of total or partial work in his usual or in a suitable occupation, irrespective of fault and irrespective of whether such a disability is the result of accident, illness, disease, physical or mental handicap, or other causes. S. 12, introduced (by request) by Senator Robinson, Arkansas, proposes to authorize an appropriation of \$5,000,000 to enable "each state to provide and operate at least one hospital bed for tubercular patients to each annual death from tuberculosis." S. 325, introduced by Senator Hatch, New Mexico, proposes to prohibit the shipment and transportation in interstate or foreign commerce of cannabis and its derivatives and compounds, except when shipped or transported for medical and legitimate uses by the producer, manufacturer or dealer to licensed physicians, surgeons, dentists, pharmacists, druggists and veterinarians, under such rules and regulations as shall be prescribed by the Commissioner of Narcotics. A similar bill in the House, H. R. 229, introduced by Representative Fish, New York, proposes to amend the Narcotic Drugs Import and Export Act to provide that no cannabis indica, cannabis sativa, or cannabis americana may be imported for the purpose of making marihuana, or for any other purpose. H. R. 119, introduced by Representative Beiter, New York, proposes to extend the benefits of the United States Public Health Service to certain seamen. H. R. 136, introduced by Representative Cochran, Missouri, proposes to authorize the Reconstruction Finance Corporation to make loans to any public or private hospital organized under the laws of any state on the same terms and conditions that are applicable in the case of loans to financial institutions. H. R. 216, introduced by Representative Lemke, North Dakota, proposes to authorize the erection of an addition to the existing Veterans' Administration facility, Fargo, N. D., such addition to consist of 100 beds for the care and treatment of general medical and surgical disabilities. H. R. 279, introduced (by request) by Representative Celler, New York, proposes to enact a "Workers' Unemployment and Social Insurance Act" and to direct the Secretary of Labor to establish forms of social insurance to pay workers and farmers for loss of wages because of part-time work, sickness, accident, old age or maternity. H. R. 1555, introduced by Delegate Dimond, Alaska, proposes to authorize the Secretary of the Interior to establish a hospital for the insane of Alaska. H. R. 1560, introduced by Delegate Dimond, Alaska, proposes to extend the benefits of the United States Public Health Service to any person operating or employed on board certain vessels engaged in fishing operations. H. R. 1952, introduced by Representative Buchanan, Texas, proposes to include the name of Roger P. Ames among those honored by the act recognizing the service rendered by Major Walter Reed in the discovery of the cause and means of transmission of yellow fever. H. R. 1962, introduced by Representative Secrest, Ohio, proposes to establish a Bureau of Veterans' Affairs in the Department of the Treasury with the Commissioner of Veterans' Affairs at the head thereof, to abolish the Veterans' Administration and to transfer its functions to such bureau, to adjust and equalize pensions of veterans and widows and dependents of veterans and for other purposes.

## Deaths in Other Countries

**Sir David Semple**, first director of the Pasteur Institute of India and later director of the Central Research Institute of India, director general of public health of Egypt, 1913-1920, died in London, January 7, aged 80.

**Dr. David Fraser-Harris**, at various times associated with the faculties of Birmingham, Glasgow and St. Andrews universities and Dalhousie University, Halifax, N. S.; author of various publications on nerves and sleep; died January 3, London, aged 69.

**Sir Grafton Elliott Smith**, formerly professor of anatomy at the University of London, the University of Manchester and the Egyptian Government School of Medicine and for many years a member of the General Medical Council of Great Britain; known especially for his anthropological researches and studies; died January 1, at Broadstairs, England, aged 70.

it is that these principles be preserved. The medical profession everywhere should do its utmost to urge on all legislators who are concerned with these matters the desirability of recognizing this point of view in any legislation that may be adopted.

### NONSPECIFIC THERAPY

The practicing physician is frequently confronted with the necessity of doing something for his patient. A written prescription represents a positive action. Medication by syringe and needle, a measure carried out on the patient by the physician himself, is even more tangible and becomes a constant temptation. The extensive use of subcutaneous, intramuscular and intravenous therapy in other countries, the unwarranted enthusiasm of uncritical but vocal practitioners, the pressure from a wide circle of charlatans, the steady stream of literature emanating largely from the advertisers, the extravagant and untested claims of the manufacturers, all have given an undeserved stimulus to parenteral therapy and bid fair to make "needle men" of many physicians. The conservative, experienced practitioner, having been through these various "cycles," will explain to his patient why he does not endorse such a procedure and by his manner and conscientious care avoid driving his patient to the opportunists. He more than any other, if he is free from prejudices, is in the best position to know what a given therapy offers and whether or not he is justified in using it. He realizes also that any medication with which an effective dose can be given by mouth is preferable to one that requires introduction beneath the skin or into a vein.

The entire subject of nonspecific therapy was extensively and critically reviewed in *THE JOURNAL* a year ago in papers by Hektoen<sup>1</sup> and Cecil.<sup>2</sup> In these articles what might be expected from such treatment, its modus operandi, and specific instructions in its use were discussed at length. The differences between nonspecific therapy and nonspecific foreign protein therapy were cited, and the single aim of both, namely, "nonspecific shock" and stimulation of the reticulo-endothelial system as an aid to the bodily defenses, was pointed out. If a chemical agent with a wide margin of safety is capable of producing the same effects, it would seem quite logical to use it. There are undoubted instances when a sluggish response on the part of the host to both acute and chronic infections gives the invading disease process an advantage that may make it more difficult, if not impossible, to overcome. In such instances some help is of real value. However, the use of a nonspecific protein, while it may be shown even with adequate control observations to be effective, still in all probability leaves the host sensitized to the material used and possibly to many related substances. It has also been

demonstrated that the presence of one sensitivity increases the chances of acquiring others subsequently, a consideration not to be looked on lightly in view of the apparent increase in allergic diseases. Even the use of vaccines has been viewed askance on account of its possible relationship to amyloidosis.

In this issue of *THE JOURNAL* Bernstein and Ginsberg<sup>3</sup> report a case of hypersensitivity to milk occurring during a course of treatment with a milk derivative. The disadvantages of such therapy are pointed out. If "protein shock" is wanted, the danger of sensitization to this protein must be realized and reasonable precaution exercised in the selection of the protein to be used. Every effort should be made to choose the material least likely to occur in the patient's dietary or therapeutic environment. Many of these patients, as in the case under discussion, are polysensitive already and an increased sensitization from protein therapy is unlikely. However, the use of this therapeutic measure has not been, and will not be, wisely restricted without frequent reminders of its dangers. No doubt it has a real place in the therapeutic armamentarium, but in the light of our present knowledge we should do well to remember the old adage *noli nocere*, "do not harm."

## Current Comment

### EXTENSION OF MEDICAL SERVICE TO THE INDIGENT

For at least a quarter of a century the medical profession has been giving special consideration to the scientific, economic and social problems of providing medical care for all the people of a standard at least as good as that which now prevails. The House of Delegates of the Association has established definite principles to guide the medical profession in these matters. The fundamental points set forth in the policies established by the American Medical Association have been determined primarily with a view to conserving for medicine in the changing times those principles which are fundamental to the advancement of medical science and the best quality of medical service. Throughout the United States today hundreds of experiments in new forms of medical practice are being conducted—many of them under the auspices of organized medicine—with a view to meeting the needs that the changes in our civilization have made evident. Recognizing the situation that has developed, the Board of Trustees at a special session held in Chicago last week adopted the following resolution as a still further evidence of the willingness of organized medicine to do its utmost to meet these problems:

"In the past, the medical profession has always been willing to give of its utmost for the care of those unable to pay. The available evidence indicates that today throughout the United States the

two noble lords who were members of the medical profession that their duty was to cure and not to kill? This was a bill to legalize murder and suicide. Euthanasia was contrary to the law of nature, which branded it as evil and cowardly. The bill asked them to ignore the Almighty. The archbishop of Canterbury said that this was a most difficult question, in which principle and compassion contended. It must be approached on the basis of the moral principle that no man was entitled voluntarily to take his own life. There must be some exceptions even to that principle, but it was one thing to admit exceptions and another to give authority to the counterprinciple that a man in his own interest might bring his life to an end. They must consider the effects on the public conscience of giving for the first time legal enactment to the principle that there were circumstances in which a man might for his own sake end his life. He doubted whether a man who was wracked with pain was capable of making a sound moral judgment. Would not the procedure contemplated by the bill inflict an almost intolerable strain when a man had to ask himself, for his own sake or of those dear to him, whether he should avail himself of this provision? Moreover, they could not dismiss the possibility of pressure by relatives from other than motives of compassion. Extreme cases might be left to the medical profession. If in one of them a physician decided to refrain from using means that would prolong life or to use means for the assuagement of pain that might lead to the shortening of life, was it not a perversion of language to say that he might be regarded as having committed murder or manslaughter? He would trust to the honor and judgment of the medical profession and would support the rejection of the bill.

Lord Dawson said that he would not like an impression to go out that agonizing pain was a more frequent characteristic of disease than it really was. It would not be correct to say that most cases of cancer were characterized by agonizing pain. There was much more control of pain today than existed years ago. Medical opinion had changed on this question. Fifty years ago the profession concentrated on the maintenance of life, in spite of the nature of the illness and even sometimes the imminence of death. It was thought that it was the duty of the physician to continue the struggle for life right up to the end. That had changed. There had gradually crept into medical as into lay opinion the feeling that one should make the act of dying more gentle and peaceful, even if it did involve curtailment of the end of life. The question should be left to the gentle and slow growth of opinion, both in the public and in the profession. A woman had incurable disease and incomparable suffering for nine years but continued to work to maintain her family. Eventually, crushed by pain, she asked for a timely death. Was the submerging of her sufferings to be denied her because death might be delayed three or four months? His view was that it should not, but there were no two people alike, and only her own physician should decide whether her desire for death was something more than a passing effect of suffering. He could not conceive a more intimate relation than that between a patient mortally ill and her physician. If passed, this bill would destroy the relation. The very idea of the sick chamber being visited by officials, the patient being treated like a case of insanity, was something so opposite from the attitude of the physician that, far from permitting the general growth of euthanasia, it would have the opposite effect. Physicians would hesitate to touch it. They would not like to introduce such an atmosphere into the sick chamber.

Lord Horder said that he did not think that this was a matter on which the medical profession should be asked to give a lead. Indeed, he was sorry that physicians had joined the movement and associated themselves with propaganda in favor of the bill. Physicians, at least in this country, were

sympathetic toward the modern efforts to secure biologic control before life began and while it lasted. But in the matter of putting an end to life, surely a new principle entered, which he submitted was outside the physician's reference, which was very clear: to cure disease safely and quickly, and, if that could not be achieved, his duty was to prolong life as long as might be and relieve pain both bodily and mental. According to the bill, euthanasia would be administered by others than the usual attendant; but was not that very fact serious? The intimate relations between physician and patient, especially toward the close of life, would be replaced by the introduction of strangers. Was that in the patient's interest? The criteria which justified the termination of life would be extremely difficult, so difficult that he would hesitate to undertake so great a responsibility as was placed on the referee. The incurability of disease was never more than an estimate. The bill would apply mainly to cases of cancer. There were cases today of persons suffering from that disease who were living free from pain as the result of advances made in treatment. With the prospect of further advances in the near future, the criteria of fatality would become more difficult. Never were so many means of relieving pain available as was the case today.

The bill was rejected by 35 votes to 14. It is remarkable that the voting was not more onesided, considering that both the clerical and the medical members of the house opposed it and that the debate was almost entirely onesided. The only point made against the opponents was that they had admitted that in certain cases the physician must act on his own initiative in terminating suffering. That put on him a heavier responsibility than the bill would place on him. During the discussion which took place in the medical press after the proposal to legalize voluntary euthanasia was brought forward, some physicians declared that they had acted in this way. As hinted in the debate in the house of lords, it is not necessary for a physician to break the law. In extreme cases he can quite legally prescribe narcotics in doses which will relieve pain regardless of any question of danger.

#### Methods of Dealing with Air Attacks

Elaborate precautions continue to be taken against one of the latest developments of civilization—air attacks on the civilian population. The government is manufacturing 30 million gas masks in a factory recently acquired for the purpose. They will be kept in stores dotted all over the country in readiness for use. They will not be distributed in peace time, because they are delicately constructed and, if entrusted to the keeping of the public, might be found useless when the time came for their use. The instruction of physicians in the dangers of air attacks and the precautions against them has begun. At a meeting organized by the Medical Practitioners Union, Major Stuart Blackmore of the Home Office delivered an address. He said that the three major dangers of air attacks were high explosive bombs, incendiary bombs and gas bombs. He placed gas last because in spite of its extraordinary dangers to an untrained population—as shown recently in Abyssinia—it was the least dangerous of the three if people had a proper degree of training and equipment. A high explosive bomb was a threat against which it was practically impossible to provide adequate protection. The object of the incendiary bomb was to produce widespread fire. For that reason it was not large, weighing about 2 pounds. It was much more difficult to deal with a large number of small sources of fire than with a small number of large sources. Incendiary bombs were provided with their own oxygen and it was undesirable to put water or chemical extinguishers on them. They burned at such a high temperature that a chemical applied to them would be decomposed and give off dangerous gases. Water and extinguishers were applied to the area surrounding the fire.

longitudinal ridging and occasional sloughing, subcutaneous edema probably of cardiorenal origin, peripheral neuritis, and protracted gastro-intestinal disturbances. Urine analysis revealed selenium in quantities of from 2 to 133 micrograms per hundred cubic centimeters in more than 92 per cent of the subjects. These symptoms and appearances may be manifestations of the poisoning; it is important for the health of the rural population in the involved areas that their relative clinical significance be determined.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARKANSAS

**Personal**—Dr. Walter W. Brown, Williford, has been appointed coroner for Sharp County, and Dr. George R. Siegel, Clarksville, for Johnson County. Dr. Bert B. Bruce, Alma, has been elected coroner of Crawford County.

**Committee for Control of Syphilis**—The Arkansas Medical Society has appointed a committee on the control of syphilis with the following members: Drs. Louie G. Martin, Hot Springs National Park; Davis W. Goldstein, Fort Smith, and George F. Jackson, Little Rock. The first meeting was held December 15.

**Secretaries' Conference**—The second annual conference of county medical society secretaries in Arkansas was held at the Hotel Marion, Little Rock, January 5. The following program was presented:

- Dr. George B. Fletcher, Hot Springs National Park, president, state medical society, Compulsory Health Insurance.
- Dr. Lee Vallette Parmley, Little Rock, Medical Legislation.
- Dr. William B. Grayson, Little Rock, How the Social Security Act Works.
- Dr. Albert S. Buchanan, Prescott, Problems of the State Medical Board.
- Omar Throgmorton, Little Rock, Malpractice: Cause, Prevention and Defense.
- Mac F. Cahal, executive secretary, Sedgwick County Medical Society, Wichita, Kan., The Modern Aggressive County Medical Society: An Instrument of Value to the Private Practitioner.

### CALIFORNIA

**Society News**—Dr. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, will discuss "Medical Economics" before the San Francisco County Medical Society February 4.—Dr. Arthur E. Hertzler, Halstead, Kan., discussed "Malignant Tumors of the Colon and Rectum, with Emphasis on Diagnosis and Treatment" before the Los Angeles Cancer Society, December 14.—Among others, Dr. Louis K. Guggenheim, St. Louis, addressed the Los Angeles Society of Ophthalmology and Otolaryngology, December 21, on "The Pathogenesis of Otosclerosis."

**Course for Sanitary Inspectors**—The University of California has organized a second training course for sanitary inspectors, continuing its drive to assist state health departments in training adequate public health personnel. The course will run from February 8 through May 4 under the direction of Karl F. Meyer, Ph.D., professor of Bacteriology, University of California Medical School, and director of the Hooper Foundation for Medical Research, San Francisco. Eight weeks will be given to lectures, conferences, laboratory practice and group field trips, and the final four weeks will consist of practical study in county and city health departments.

### DISTRICT OF COLUMBIA

**Medical Bills in Congress**—*Bills Introduced*: H. R. 220, introduced by Representative Lemke, North Dakota, proposes that no form of vaccination or inoculation shall be made a condition precedent, in the District of Columbia, for the admission of any person to any public or private school or college, or for the exercise of any right, the performance of any duty or the enjoyment of any privilege by any person. S. 84, introduced by Senator White, Maine, proposes to provide for the issuance of a license to Dr. Ralph Charles Stuart to practice the healing art in the District of Columbia.

**Civic Award to Dr. Hall**—Dr. Custis Lee Hall, assistant professor of orthopedic surgery, George Washington University School of Medicine, was presented, January 4, with the first Citizens' Service Award for 1936. The cup, which will be awarded annually to the citizen who is considered to have rendered the most unselfish service to the whole community, is provided by the *Washington Times*; the recipient is selected by a representative citizens' committee. Dr. Hall was chosen for his work among crippled children and adults. He is a native of Washington and graduated from George Washington University School of Medicine in 1912. He was formerly president of the Washington Medical and Surgical Society and of the George Washington University Medical Society.

### ILLINOIS

**Hospital News**—Dr. William DeHollander, Green Bay, Wis., has been placed in charge of the x-ray department of St. John's Hospital, Springfield, succeeding Dr. Lawrence M. Hilt, who has been appointed to a similar position with Butterworth Hospital, Grand Rapids, Mich.

**Society News**—Dr. Walter Schiller, University of Vienna, will discuss gynecologic endocrinology before the Springfield Medical Club, January 19.—At a meeting of the Peoria City Medical Society, Peoria, January 5, Carlos I. Reed, Ph.D., and Dr. Irving E. Steck, Chicago, spoke on "Mineral Metabolism in Arthritis Under Treatment with Vitamin D" and "Clinical Experience in Treating Arthritis with Vitamin D" respectively.—Dr. Charles J. Drucek, Chicago, addressed the McLean County Medical Society in Bloomington, January 12, on "What Brings the Anorectal Patient to the Doctor."

### Chicago

**The Hektoen Lecture**—Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, will deliver the thirteenth Ludvig Hektoen Lecture of the Frank Billings Foundation before the Institute of Medicine of Chicago, January 22. The subject of his illustrated lecture will be "Vaccinia."

**Dr. Parran Will Give Gehrman Lectures**—Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., will deliver the Gehrman Lectures for 1936-1937 at the University of Illinois College of Medicine, January 25, 26 and 27. His subjects will be "Health as a Factor in Social Security," "Industrial Hygiene" and "Syphilis."

**Personal**—Dr. Harry Gradle has been appointed consulting ophthalmologist to the Indian Medical Service, U. S. Department of Interior.—Arnold Emch, Ph.D., has been appointed executive director of the Chicago Hospital Council, succeeding Perry Addleman, who has been appointed to a similar position with the Hospital Service Corporation.

**Professor Stieglitz Dies**—Julius O. Stieglitz, Ph.D., professor emeritus of chemistry, University of Chicago, died of coronary occlusion and lobar pneumonia at Chicago Memorial Hospital, January 10, aged 69. Dr. Stieglitz was born in Hoboken, N. J., May 26, 1867. He received the degree of doctor of philosophy from the University of Berlin in 1889. Clark University awarded him an honorary degree of doctor of science in 1909. Identified with the University of Chicago since 1892, he was professor of chemistry from 1905 to 1933, when he was made professor emeritus. He was director of analytic chemistry at the university from 1909 to 1915, director of the university laboratories, 1912-1924, and chairman of the department of chemistry, 1915-1933. Dr. Stieglitz was a charter member of the Council on Pharmacy and Chemistry of the American Medical Association, serving continuously from 1905 to 1926, and was chairman of its Committee on Rules and Procedure. Although most of his investigative work was in the difficult field of physical chemistry applied to organic chemistry, this never affected his interest in the application of chemistry to science and medicine. From 1917 to 1919 he was chairman of the Committee on Synthetic Drugs of the Federal Trade Commission. The purpose of this committee was to aid in the manufacture of drugs on which Germans held patents and to give names to the American preparations. Thus this committee aided in working out methods of manufacture of arsphenamine, cinchophen, barbitol, procaine and other substances and coined these names. He was a member of the International Commission on Annual Tables Constants, 1915-1921, and a member of the Institute of Medicine of Chicago. From 1917 to 1919 he was chairman of the committee on synthetic drugs of the National Research Council and vice chairman of the division of chemistry, 1919-1921. Since 1918 he had served as a special expert for the Hygienic Laboratory of the U. S. Public Health Service. He edited the widely distributed book "Chemistry in Medicine," published under the

remarks that this can be easily circumvented by renting adjacent rooms or perhaps, as he states, there will be created a new trade as now exists in the United States; namely, that of "renting baggage" for a small fee. There will still remain, for those able to pay a higher sum, houses of assignation. The closing of "tolerated" houses will result in increase of street soliciting, which will render control of venereal diseases more difficult than at present, when the inmates of the "tolerated" houses are examined twice a week by medical inspectors of the police departments. The existing system of "segregation" with its strict control will be superseded by that of "scattering" and less perfect medical supervision, so that the number suffering from venereal diseases will be greater than at present. Bizard pleads for an amelioration instead of suppression of "tolerated" houses, citing the measures taken in Italy, which has prohibited street soliciting but allowed "tolerated" houses to exist without any special signs or lights indicating the character of their trade. Such a plan will do more to check venereal diseases than that of forcing prostitutes to go on the streets.

#### Dedication of Eastman Dental Clinic in Paris

Work has progressed so rapidly on the million dollar Eastman Dental Clinic, now under construction in Paris, that Dr. Harvey J. Burkhart, director of the Rochester Dental Dispensary and general administrator of the Eastman Foundation, announced recently that it is hoped to finish the entire building in time to hold the dedication ceremonies on July 4, 1937. The president of the French Republic, Mr. Lebrun, Ambassador William C. Bullitt and a number of other leading French and American personalities will be invited to take part in the ceremonies. The clinic was designed to provide free dental service for children less than 16 years of age who are unable to pay. The clinic occupies a large area, and the open land surrounding the clinic will be converted into parks and playgrounds. The work of the Paris Eastman Clinic will be based on that carried out at Rochester, and it should serve as a center for dentists and dental surgeons to carry on research and postgraduate work. It will also aim to teach children and parents the need and value of regular dental work throughout their lives.

#### Meeting of French Gynecologic Society

The 1937 meeting of the French Gynecologic Society will be held May 15-18 at Toulouse. The subject chosen for general discussion is cancer of the cervix, and papers will be read on the etiology and pathology, diagnosis, influence on the urinary tract, operations during pregnancy, treatment with radium, x-rays or electrocoagulation, complications of radiotherapy, cancer of the cervical stump after subtotal hysterectomy, recurrences and metastases. Those who desire to attend are requested to write to Dr. Maurice Fabre, 1 rue Jules-Lefebvre, Paris.

#### Death of Prof. Victor Pauchet

The surgeon Prof. Victor Pauchet died recently in Amiens, where he had lived since his retirement in 1935. He was born in Amiens, where he practiced until shortly after the World War. He was professor of surgery at the local medical school. His reputation as one of the most able surgeons on the continent reached its climax during his residence in Paris (since 1919). His contributions to the literature of gastro-intestinal surgery were read all over the world. His book on operative technic has been translated into Spanish and English. The clinics which Professor Pauchet held twice a week at the Hôpital St. Michel were attended by surgeons from every country. During the summer of 1935 he sustained a severe concussion of the brain, from which he never fully recovered. His death was due to a cerebral hemorrhage following a fall. France loses through the death of Professor Pauchet one of its most prominent figures in surgery of the alimentary tract.

## BERLIN

(From Our Regular Correspondent)

Nov. 23, 1935

### Growth of German Sick Insurance

The latest figures on the growth of the German sick insurance have just been made public. More recent supplementary data have been added to the statistics that were published in *THE JOURNAL* June 27, 1936, page 2250. The sick insurance societies continued to decrease in number during 1935. In the year 1934 there were 6,190 such societies, but in 1935 only 5,520 were listed. This decline in number is a consequence of a tendency to merge on the part of the smaller sick insurance societies. Of a total membership of 20,835,000 persons, 13,700,000 were male subjects and 7,200,000 were female. According to the report of the National Bureau of Statistics, the average number of members during 1934 was 19,900,000, representing an increase of around 1,400,000 more than the year 1933; in the year 1935 the corresponding average was 20,900,000 members, an excess of 1,000,000 more than in the previous year, 1934. The administrative personnel of the sick insurance societies numbered 35,635 persons in 1934 and 36,229 persons in 1935. Since 1924 the number of society employees has been increased by nearly 10,000 persons.

The cases of illness recorded in 1934 amounted to 6,400,000. These were in some way related to loss of working capacity. There were 7,400,000 such cases in 1935. Of each 4.9 cases in which the societies provided medical care (including dental treatment), one case on the average involved a loss of working capacity.

Since 1929 there has been an increase in the average duration of illness up to 1933 and then a decrease (table 1). The number of sick days, including hospital care, is given in table 2. Of 158,500,000 sick days computed for the year 1934, around 121,000,000 were days on which the patient was treated at home and received monetary benefits; that is, the insured were incapacitated for work on those days. For 5,900,000 other sick days, no claim of monetary benefits was involved; namely, treatment for illness was administered but the insured remained

TABLE 1.—Average Duration of Illness, 1929-1934

Year	Days
1929 .....	23.7
1930 .....	27.3
1931 .....	28.7
1932 .....	29.3
1933 .....	25.6
1934 .....	24.6

TABLE 2.—Number of Sick Days, Including Hospital Care

Year	Sick Days in Millions
1929 .....	294
1930 .....	236
1931 .....	204
1932 .....	157
1933 .....	156
1934 .....	154.5

at work. Finally, 31,600,000 of these sick days were days on which insured persons were in the hospital. Hospitalization was chiefly demanded by members of the rural sick insurance societies; that is to say, by many more of the rural population than of the urban population. Dr. Hadrich, a member of the League of Sick Insurance Physicians of Germany, reports some interesting calculations of his own in the *Deutsches Ärzteblatt*. He found that especially in the country the expenditures for physicians' honorariums were lower than the rates for hospital care. As a result of the slight remuneration received for services in the rural regions, physicians tend to emigrate at the

## NEW YORK

**Personal.**—Dr. Marion F. Loew, formerly supervisor of tuberculosis clinics in the New York City Department of Health, has been appointed assistant director on the staff of the division of maternity, infancy and child hygiene of the New York State Department of Health.—Dr. Joseph Lander, a member of the staff of Grasslands Hospital, Valhalla, since June, has been appointed assistant chief of the department of psychiatry.—Dr. Alfred M. Mead, Victor, was guest of honor at a dinner at the nurses' home of Thompson Hospital, Canandaigua, recently in celebration of his eightieth birthday. He is the senior member of the hospital staff and has practiced fifty-six years.

### New York City

**Fourth Harvey Lecture.**—Dr. Rudolf Schoenheimer, assistant professor of biologic chemistry, Columbia University College of Physicians and Surgeons, will deliver the fourth Harvey Lecture of this season at the New York Academy of Medicine, January 21, on "The Investigation of Intermediary Metabolism with the Aid of Heavy Hydrogen."

**Awards at Hospital for Joint Diseases.**—The Henry W. Frauenthal Travel Scholarship of the Hospital for Joint Diseases has been awarded to Dr. Charles J. Sutro for 1936-1937. Dr. Sutro, a graduate of Long Island College of Medicine, has been associated with the hospital since 1931 and last year held the Mr. and Mrs. Frederick Brown Orthopedic Research Fellowship. The latter fellowship, given by the president of the hospital, was awarded to Dr. Aaron M. Gold for 1937. Dr. Gold, who was graduated from Harvard University Medical School in 1931, also held this fellowship for 1936.

**Changes at Long Island College.**—Dr. Charles A. Weymuller, assistant clinical professor of pediatrics at Long Island College of Medicine, has been promoted to be professor of pediatrics. Dr. Lambert Krahulik has been promoted to be professor of clinical pediatrics, and Drs. Stanley S. Lamm and Lewis A. Koch, Brooklyn, and David H. Shelling, Baltimore, have been appointed assistant clinical professors of pediatrics. Dr. Carl H. Laws, professor of clinical pediatrics, has been appointed to a newly established professorship of child health and welfare in the division of preventive medicine and community health.

**Professor Benedict Is Dead.**—Stanley R. Benedict, Ph.D., professor of chemical pathology, Cornell University Medical College, died December 21, aged 52, at his home in Elmsford. Dr. Benedict became associated with Cornell in 1910 as assistant professor and became professor and head of the department of biochemistry in 1912. He was known as the originator of the Benedict solution for determination of sugar content in diabetes and other tests for chemical analysis of body fluids. He was president of the Society of Biological Chemists in 1920 and at the time of his death was managing editor of the *American Journal of Biochemistry*.

## OHIO

**"Diet Expert" Brooks Banished.**—Michael Erim Brooks, self-styled "psychologist," "mindologist," "health lecturer" and "diet expert," was recently convicted in Toledo of practicing medicine without a license. He was fined \$1,000, but the fine was reduced to \$250 on his promise to leave the state. Brooks had his office and lecture hall in the basement of a Toledo church and gave lectures weekly at \$5 per person. He admitted that his income was \$800 a month from the lectures and "treatment." At the request of the Toledo Academy of Medicine, the State Medical Board investigated with the cooperation of the county prosecutor, the police department and the Toledo Better Business Bureau. It is said that Brooks was ordained to the Methodist ministry in 1923 and was at one time advance man for a medicine show. The *JOURNAL* reported May 2, 1931, page 1513, that one M. E. Brooks had been fined \$400 in San Diego for having advertised in violation of the medical practice act. He is said to have called himself "Dr. Brooks" and to have claimed that he cured disease through diet and a preparation called "Vivogen."

## OKLAHOMA

**Society News.**—Drs. Henry S. Browne and Joseph Fulcher, Tulsa, addressed the November meeting of the Craig County Medical Society on genito-urinary diseases.—At the November meeting of the Logan County Medical Society in Guthrie, Drs. Hervey A. Foerster and Anson L. Clark, Oklahoma City, spoke on "Common Skin Diseases" and "Mandelic Acid Treatment in Urinary Tract Infections" respectively.

**Bill Enacted.**—H. 19-X was approved by the governor, January 4. This law appropriates \$100,000 for the fiscal year ending June 30, 1937, to provide funds for the state board of public welfare for grants to the several counties for medical, dental, osteopathic, ocular, surgical and hospital treatment of indigents. The board is to grant not to exceed \$1,000 monthly to each county showing the necessity therefor, to be disbursed by the particular county welfare board, which is to provide hospitalization for indigents in need of such care and to furnish and pay for a "medical doctor, dentist, osteopath or optometrist" of the patient's choice.

## PENNSYLVANIA

**County Society Secretaries' Conference.**—The thirtieth annual conference of secretaries of county medical societies and the editors of their publications will be held at the Penn-Harris Hotel, Harrisburg, February 2. Subjects proposed for discussion include proposed health legislation, how to deal with unlicensed practitioners, interesting programs for small societies, county plans for medical service to indigent and low income groups, methods for increasing county society membership and collecting dues, hospitalization insurance, the county society and its membership in politics. Among the speakers will be Drs. Charles Gordon Heyd, New York, President of the American Medical Association; Maxwell J. Lick, Erie, president of the Medical Society of the State of Pennsylvania, and representatives of the county societies that are developing collection and sickness service plans.

### Philadelphia

**Personal.**—The staff of the Joseph Price Memorial Hospital gave a dinner in honor of Dr. James W. Kennedy, surgeon-in-chief for twenty-five years, December 5. Dr. Samuel R. Shaner was toastmaster. Dr. Kennedy is president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons.

**Society News.**—Dr. Gregor W. McGregor, Toronto, addressed the Philadelphia Laryngological Society, January 5, on "The Histopathology of Mastoiditis and the Correlation of the Various Diseases Concerned."—Dr. Samuel A. Cosgrove, Jersey City, addressed the Obstetrical Society of Philadelphia, January 7, on surgical complications of pregnancy.—At a meeting of the Philadelphia Roentgen Ray Society, January 7, the speakers were Drs. Stanley P. Reimann, on "Biological Bases for the Growth and Regression of the Breast"; Jacob Gershon-Cohen, "Roentgen Diagnosis of Breast Tumors" and George P. Müller, "Present Day Concepts in the Treatment of Malignancy of the Breast."

## VIRGINIA

**Personal.**—Dr. Jesse B. Hopkins, Pound, has been appointed to the staff of the bureau of communicable diseases of the state department of health.—Dr. Greer Baughman was appointed surgeon to the fire department of Richmond in December.

**Health at Richmond.**—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended January 2, indicate that the highest mortality rate (31.4) appeared for Richmond and that the rate for the group of cities was 14.5. The mortality rate for Richmond for the corresponding week of 1936 was 18.2 and that for the group of cities, 13.8. Caution is necessary in interpreting these weekly figures, as they fluctuate widely. The fact that a city is a hospital center for a large area or that it has a large Negro population may tend to increase the death rate.

## WASHINGTON

**Society News.**—At a meeting of the King County Medical Society, Seattle, January 18, the speakers will be Drs. Donald J. Thorp and David Metheny, on "Does the Bony Pelvis Enlarge During Pregnancy?" and "Instrumental Perforation of the Rectosigmoid" respectively.

**New State Health Officer.**—Dr. Donald G. Evans, Seattle, has been appointed commissioner of health for the state of Washington, succeeding Dr. Erval R. Coffey, who had been on leave from the U. S. Public Health Service for the past three and a half years. Dr. Evans is 32 years old and a graduate of Iowa State University School of Medicine. He spent his internship at the Seattle General Hospital and recently received a certificate in public health at Johns Hopkins University. At one time he was associated with the health department of Seattle and for the past year has been assistant state director of health.

## MARRIAGES

## BELGIUM

(From Our Regular Correspondent)

Nov. 16, 1936.

## Ancylostomiasis in Belgium

Dr. Timbal has submitted to the International Bureau of Hygiene a review of the more important measures that have been taken to combat ancylostomiasis in Belgium. First Professor Malvoz, with the aid of the provincial authorities of Liège, the colliery association and the workers' mutual aid organizations, was able to establish a laboratory, the activities of which included the search for the causative organisms in stools and the institution of therapeutic measures (oral administration of ethereal extract of *Aspidium filixmas* twice every forty-eight hours). Later on a royal decree of Oct. 29, 1904,

TABLE 1.—*Ancylostomiasis Among Belgian Miners*

Mining Region	Percentual Morbidity of Miners	
	1904-1906	1908-1910
Haute Meuse .....	10.8	5.1
Plateau Ans-Montegnée .....	20.2	5.3
Liège and Basse-Meuse .....	8.6	8.5
Plateau de Herve .....	5.1	1.9
Averages .....	11.4	5.3

provided for the detection and treatment of worm carriers. A law of Dec. 31, 1920, stipulates that before any worker shall be employed in a coal mine his excreta shall have been examined microscopically within the preceding forty days by an approved physician and found to be negative. A second examination must also be made from thirty to forty days subsequent to the first. A worker who transfers from one mine to another must undergo reexamination. Further examinations for checking on the condition of the men are optional. A miner who presents the disease must undergo a course of curative treatment in a hospital approved by the bureau of mines. The mine operator must bear the expenses of such curative treatment and must compensate the worker for wages lost on account of the recheck examinations. In the province of Liège all examinations are carried on at a central dispensary and this arrangement facilitates the observation of a worker who successively

TABLE 2.—*Morbidity Since 1914*

Year	Number of Examinations	Number Positive	Percentage Positive
1915 .....	24,278	115	0.47
1920 .....	17,624	53	0.19
1921 .....	19,359	3	0.015
1922 .....	22,614	15	0.066
1923 .....	27,084	2	0.007
1924 .....	27,508	12	0.043
1925 .....	20,578	2	0.009
1926 .....	25,109	2	0.008
1927 .....	18,443	13	0.07
1928 .....	19,094	10	0.052
1929 .....	23,790	10	0.042
1930 .....	26,100	11	0.041
1931 .....	14,190	3	0.021
1932 .....	5,764	1	0.017
1933 .....	6,487	0	0.000
1934 .....	3,395	1	0.029
1935 .....	6,242	2	0.032

transfers his services from mine to mine. The law also compels the management of infected mines to provide a sufficient number of latrines at the surface and portable buckets to be used by the men below ground for sanitary purposes. Company regulations must forbid the deposit of excrement within the mine or anywhere else but in the latrines and buckets. Thanks to these various measures, the percentage of infected miners underwent a rapid decrease, as the morbidity table for

the years from 1904 to 1906 (first column) and from 1908 to 1910 (second column) shows. The incidence of worm carriers in the coal mines of the area was estimated at 26 per cent. Since that time the situation has continued to improve, as table 2 shows. There has been that ancylostomiasis has been extirpated, or nearly so, from the Liège area and the same is true of other regions in Belgium.

## The Red Cross in the Congo

The Croix Rouge du Congo has published a report of its activities during 1935. It is an eloquent record of the work accomplished by this important branch of the Red Cross. The Congo Red Cross, founded in 1924 and provided with laws and by-laws, received the status of a corporation by a royal decree of May 14, 1926. As early as 1925 Dr. Gonzemius founded the organization's first medical center for the care of the native population, an enterprise which was at once enthusiastically received. In 1921 Professor Deby of the Royal Colonial Institute reorganized the antileprosy station at Pawa, which since that time has become an extremely important center for research on the epidemiology and therapeutics of leprosy. The well equipped Pawa laboratory is headed by Dr. Vanbreuseghem. Thanks to the energy and efficiency of Dr. Gonzemius and the intelligent assistance of Mme. Gonzemius, lying-in hospitals and consulting centers for nursing mothers have been established and training of the native midwives has been encouraged.

The statistics are eloquent of the admirable manner in which both the administrative officials and the personnel have acquitted themselves in this beneficent work. From 1926 to 1935 the number of hospitals increased from one to seven, the number of hospitalized patients from 200 to 3,000. Dispensaries increased from two to twenty-nine, the number of cases treated therein from 20,000 to 100,000 and the number of examinations from 10,000 to 800,000.

## Marriages

- GEORGE CLEGG WILLIAMS, Jewell Ridge, Va., to Miss Muriel Elizabeth Smith of Wilmington, N. C., Oct. 3, 1936.  
 ROBERT HAWTHORNE WYLLIE JR., New York, to Miss Jane Deyo Voorhees of Hartford, Conn., Oct. 10, 1936.  
 THOMAS JEFFERSON TAYLOR, Scotland Neck, N. C., to Miss Doris Darling of Endicott, N. Y., Oct. 3, 1936.  
 SAMUEL T. BERNSON, Newark, N. J., to Miss Ethel Grayce Esterman of Green Bay, Wis., Sept. 19, 1936.  
 CLARRY CLYDE TRICE, Richmond, Va., to Miss Mary Alice Farrell of High Point, N. C., Oct. 3, 1936.  
 THOMAS IRVIN WILLINGHAM to Miss Fort Scott Meade, both of Atlanta, Ga., in October 1936.  
 JOHN MOKMA VAN DE ERVE to Miss Caroline Anderson, both of Charleston, S. C., Oct. 24, 1936.  
 ALBERT W. THOMPSON to Mrs. Lula Campbell, both of O'Donnell, Texas, Sept. 26, 1936.  
 JOSEPH D. MILLARD to Miss Margaret Ludes, both of Shamokin, Pa., in October 1936.  
 JAMES A. WARD, Golconda, Ill., to Miss Thelma McFarland of Louisville, Ky., Oct. 10, 1936.  
 CARL H. JOHNSON, Williamsport, Pa., to Miss Nancy K. of Gettysburg, Oct. 30, 1936.  
 JOSEPH EDWARD MACMANUS to Miss Leon N. H. of New York, Nov. 7, 1936.  
 RICHARD GLENN PERCI, Kilgore, Texas, to Miss Ma-John of Helper, Utah, recently.  
 JOHN W. WHITEHEAD, Logan, W. Va., to Miss Grace H. in Raleigh, Oct. 3, 1936.  
 ERNO DISTRICH BAYNOR, Phoenix, Ariz., to Miss L. of Tucson, recently.

#### Physicians in Politics

For a Chadwick lecture Sir Francis Fremantle, M.P., a retired health officer, took as a subject "The Doctor's Mandate in Parliament." He said that the doctor's mandate was to express the special experience of the profession and its knowledge of life in every phase and every section of the community, both on matters of health and on those of general policy and administration. On health matters the physician had his great opportunity. Postwar health legislation had developed the whole machinery of public health to a remarkable extent, throwing the burden of its administration on local authorities with generous expert and financial assistance from the government. The law had been simplified by consolidation; the auxiliary professions—nurses, midwives, dentists, architects, health visitors—had been recognized and helped. Probably the greatest measure of all was the local government act, with its block grant, the conversion of the poor law into public assistance under county councils and the systematic arrangement of local administration. The effects of that work were reflected in the twenty-five years of the late king's reign by the marked decline or elimination of some diseases (e. g., the fall of typhoid deaths from over 3,000 to 160 a year), the fall of the death rate by nearly 4 per thousand and of infant mortality by 71 per thousand and the increase in the expectation of life by seven years.

Medical members of parliament had not, of course, been the chief movers in these reforms but they had played a considerable part. Before the war they had Lord Lister and Lord Ilkerton (previously Sir Balthazar Foster) in the house of lords, they had an attorney general in Sir Robert Finlay, and they had Sir W. J. Collins (chairman of the London County Council) and Dr. Addison (professor of anatomy). Since the war Lords Dawson, Moynihan and Horder had served in the upper house, while Dr. Addison, Sir Auckland Geddes and Mr. Elliott had risen to cabinet rank and been responsible for much progress in health and housing. The universities had sent as members of parliament Sir Watson Cheyne, Sir George Berry, Sir E. G. Graham-Little and others. A parliamentary medical committee was formed after the war and worked in close association with the British Medical Association. It had taken an active interest in the principal bills and subjects affecting health.

On general policy and administration the medical member of parliament had no less an important part to play, which as yet was little recognized. He had a unique knowledge of the condition of the people and their mentality. He should know best both the effect of parliamentary action in the social sphere and the will of the electorate in any matter. This was of increasing importance in a democracy. He was trained to the correct method of dealing with any problem by observation of facts, diagnosis of cause, prescription of treatment and after-care or postmortem. He took party for what it was worth, essential for practical purposes but reflecting only tendencies. He saw the limitations of any policy and in his mind had achieved a synthesis which was best expressed by an all-party government. If he aimed at high office he must avoid much occupation at first with health matters or he would be damned as an expert. By such avoidance he gained experience and credit and might in the end be of the greatest service to the state, even in health matters. But even in the rank and file of politicians there was much for the doctor to do with his mandate. On him fell the privilege of dealing fearlessly in private and in public with the awkward topics—sexual questions and marriage, betting

and licensing, Sunday trading, and moral and ecclesiastical problems. He almost alone in parliament had no right to shirk the difficulties of birth control and other national dangers. He especially could see disease in the body politic at an early stage and prescribe for its elimination. His part should be of especial value in deciding root policy affecting peace and war, strikes and conciliation. He stood above all for the proper blend of material and spiritual values.

#### Proposed Extension of Public Medical Service in London

At a meeting of the council of the British Medical Association the chairman of the medicopolitical committee, Dr. Bone, brought forward a recommendation that a request for extension of the London public medical service to persons of higher income limit be acceded to, but only in those division areas of the metropolis which desired it. Sir Henry Brackenbury moved an amendment that the request be acceded to on condition that rules were laid down for the nonoperation of the extension in the event of an expression of opinion against it in any unit of the metropolitan area. If a certain number of physicians desired the extension and all the rest were indiffer-

#### Classes of Subscribers and Their Contributions

##### Class I. Incomes between \$1,250 and \$1,875

No. in Family	Annual Subscription
1 .....	\$ 7.50
2 .....	12.50
3 .....	17.50
4 .....	20.00
5 or more.....	22.50

##### Class II. Incomes between \$1,875 and \$2,375

1 .....	10.00
2 .....	15.00
3 .....	20.00
4 .....	22.50
5 or more.....	25.00

##### Class III. Incomes between \$2,375 and \$2,750

1 .....	12.50
2 .....	17.50
3 .....	22.50
4 .....	25.00
5 or more.....	27.50

ent, it was clearly right that the request should be granted. Indifference of physicians to the extension was not important, but opposition to it would be serious. The amendment was carried. The classes of subscribers and their respective contributions are given in the accompanying table. The privileges of subscribers include a general practitioner service and a supply of ordinary medicines; also, when desired by the subscriber, an annual overhaul.

#### Rejection of the Bill to Legalize Voluntary Euthanasia

The object of formation of the Voluntary Euthanasia Legalization Society was to legalize the termination of life, at the patient's desire, when he was suffering from painful incurable disease. The president was the late Lord Moynihan, who was to have introduced a bill prepared by the society in the house of lords. The second reading of the bill was moved by Lord Ponsonby, and Lord Deman seconded the motion. Viscount Fitzalan, who represented Roman Catholic opinion, said that if the bill became an act he would be sorry for the relatives of a patient, who would have a great responsibility thrust on them. He would be still more sorry for the physicians, who would have the responsibility of perpetrating the act, and he would be most sorry of all for the unfortunate patient, who would be exposed to great mental anxiety while all the formalities laid down in the bill were being prepared. Might he point out to the

**Alexander McNeish**, Leicester, Mass.; Tufts College Medical School, Boston, 1897; member of the Massachusetts Medical Society; member of the board of health and of the school board; aged 66; died, Nov. 19, 1936, in St. Petersburg, Fla.

**Joseph B. Parrott**, Church Point, La.; Tulane University of Louisiana Medical Department, New Orleans, 1892; member of the Louisiana State Medical Society; aged 66; died, Nov. 4, 1936, in the Touro Infirmary, New Orleans, of pneumonia.

**Joseph C. Springer**, Chicago; College of Physicians and Surgeons of Chicago, 1896; for many years coroner's physician and formerly criminologist to Chicago and Cook County; aged 69; died, Nov. 3, 1936, of uremia and chronic nephritis.

**Charles Campbell Parks**, Lancaster, Texas; University of Texas School of Medicine, Galveston, 1917; served during the World War; aged 46; died, Nov. 12, 1936, in the Veterans Administration Facility, Waco, of cerebral hemorrhage.

**Edward Monroe Clark**, National Military Home, Ohio; Starling-Ohio Medical College, Columbus, 1909; on the staff of the Veterans Administration Facility; aged 55; died, Nov. 18, 1936, of bullet wounds inflicted by a former patient.

**Oscar J. Kendall** ☉ San Diego, Calif.; Tulane University of Louisiana Medical Department, New Orleans, 1884; member of the examining board during the World War; aged 77; died, Nov. 18, 1936, in the Scripps Memorial Hospital.

**John William Bellomy**, Flemingsburg, Ky.; University of Louisville Medical Department, 1912; member of the Kentucky State Medical Association; aged 52; died, Nov. 17, 1936, of hypertensive heart disease and chronic nephritis.

**Frank Aquilla Rogers**, Hattiesburg, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1909; served during the World War; aged 53; died, Nov. 17, 1936, in the Veterans Administration Facility, Biloxi.

**Charles Eugene Cheek**, Fuquay Springs, N. C.; University College of Medicine, Richmond, Va., 1912; member of the Medical Society of the State of North Carolina; aged 50; died suddenly, Nov. 6, 1936, of cerebral hemorrhage.

**Lucius Henry Smith**, Palmyra, N. Y.; Syracuse University College of Medicine, 1885; member of the Medical Society of the State of New York; aged 74; died, Nov. 18, 1936, in Albany, of myocarditis and diabetes mellitus.

**Frank O'Hara Miller Jr.**, Wichita, Kan.; Louisville (Ky.) National Medical College, Medical Department, State University, 1906; member of the Kansas Medical Society; aged 61; died, Nov. 9, 1936, of chronic endocarditis.

**Otis Zalmon Bouton** ☉ Foultonville, N. Y. Albany (N. Y.) Medical College, 1898; formerly county coroner, health officer and school physician of Fultonville; aged 64; died, Nov. 7, 1936, in the Amsterdam (N. Y.) City Hospital.

**James B. Bryant**, Lawrenceville, Ill.; Louisville (Ky.) Medical College, 1889; formerly a master in chancery for Lawrence County circuit court; aged 76; died, Nov. 21, 1936, of bronchopneumonia and bulbar paralysis.

**George William McGinnis**, Raceland, Ky.; Eclectic Medical Institute, Cincinnati, 1905; aged 68; died, Nov. 5, 1936, in St. Mary's Hospital, Huntington, W. Va., of uremia, vesical calculi and hypertrophy of the prostate.

**George Mitchell Jones** ☉ Smithville, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1916; past president of the Bastrop County Medical Society; aged 46; died, Nov. 26, 1936, of pneumonia.

**Lawson Hughes**, Conroe, Texas; St. Louis College of Physicians and Surgeons, 1909; member of the State Medical Association of Texas; served during the World War; aged 63; died, Nov. 11, 1936, of heart disease.

**Samuel Bowen Hudson**, Sabinal, Texas; Barnes Medical College, St. Louis, 1898; member of the State Medical Association of Texas; served during the World War; aged 60; died in November 1936 of angina pectoris.

**Marcus Leopold Goodman**, New York; Columbia University College of Physicians and Surgeons, New York, 1909; aged 56; died, Nov. 17, 1936, of injuries received when he fell down the stairs in a patient's home.

**Joseph Henry Radford**, Galt, Ont., Canada; Victoria University Medical Department, Coburg, Ont., 1880; past president of the Ontario Medical Health Officers' Association; aged 79; was found dead, Nov. 8, 1936.

**Mary Ann Cooke**, Norwalk, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1888; aged 87; died, Nov. 13, 1936, in the Norwalk Memorial Hospital of fracture of the hip and arteriosclerosis.

**John Greene Martin** ☉ Lake Charles, La.; Dartmouth Medical School, Hanover, N. H., 1891; fellow of the American College of Surgeons; on the staff of St. Patrick's Hospital; aged 72; died, Nov. 29, 1936.

**Homer Irvin Kedney**, Detroit; Detroit College of Medicine, 1906; member of the Michigan State Medical Society; aged 62; on the staff of the Harper Hospital, where he died, Nov. 1, 1936, of pneumonia.

**Herbert Lionel Reddy**, Westmount, Que., Canada; McGill University Faculty of Medicine, Montreal, 1876; for many years medical superintendent of the Woman's General Hospital; aged 82; died, Nov. 4, 1936.

**Herbert John Wing** ☉ Hartford, Mich.; University of Illinois College of Medicine, Chicago, 1929; aged 32; on the staff of the Mercy Hospital, Benton Harbor, where he died, Nov. 8, 1936, of pneumonia.

**Eugene Way** ☉ Ventnor, N. J.; Jefferson Medical College of Philadelphia, 1879; for many years secretary of the Cape May County Medical Society; aged 79; died, Nov. 15, 1936, of carcinoma of the cecum.

**Robert Roy Kennedy** ☉ Minneapolis; Milwaukee Medical College, 1911; on the staffs of the Asbury, Swedish and St. Mary's hospitals; aged 53; died suddenly, Nov. 7, 1936, of coronary disease.

**Walter Glover Mead** ☉ Kearny, N. J.; New York Homeopathic Medical College and Hospital, 1900; anesthetist to the West Hudson Hospital; aged 61; died, Nov. 2, 1936, of angina pectoris.

**Earl Robert Devere**, Providence, R. I.; Tufts College Medical School, Boston, 1919; aged 41; died, Nov. 26, 1936, in the Rhode Island Hospital, of hypertensive cardiovascular disease and uremia.

**Walter James Williams**, Edwardsville, Ill.; Meharry Medical College, Nashville, Tenn., 1918; aged 44; died, Nov. 17, 1936, in St. Elizabeth Hospital, Granite City, of self-inflicted wounds.

**Michael Angelo Steffin**, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1919; aged 43; on the staff of St. Agnes' Hospital, where he died, Nov. 6, 1936, of typhoid fever.

**Frederick Brown Snyder** ☉ Rittman, Ohio; Temple University School of Medicine, Philadelphia, 1917; acting county health commissioner; aged 47; died suddenly, Nov. 10, 1936, of mitral stenosis.

**Arthur B. Cray**, Monticello, Ind.; Medical College of Indiana, Indianapolis, 1903; World War veteran; aged 61; died, Nov. 8, 1936, in the Methodist Hospital, Indianapolis, of heart disease.

**David Lloyd Morgan** ☉ Emporia, Kan.; Louisville (Ky.) Medical College, 1904; on the staff of St. Mary's Hospital; aged 61; died, Nov. 23, 1936, of a self-inflicted incised wound of the throat.

**Edgar Lee Gleaves**, Nashville, Tenn.; University of Nashville Medical Department, 1898; member of the Tennessee State Medical Association; aged 69; died, Nov. 1, 1936, of cerebral hemorrhage.

**William Elden Doane**, North Bend, Neb.; St. Louis University School of Medicine, 1906; aged 58; died, Nov. 17, 1936, in the Veterans Administration Facility, Hines, Ill., of carcinoma of the lung.

**George Robert Lee Cole** ☉ Washington, D. C.; University of Maryland School of Medicine, Baltimore, 1887; aged 72; died, Nov. 10, 1936, of arteriosclerosis and cerebral hemorrhage.

**George Willson Murdock**, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1867; Civil War veteran; aged 93; died, Oct. 29, 1936.

**John Bowman Darling**, St. Paul; Rush Medical College, Chicago, 1882; an Affiliate Fellow of the American Medical Association; aged 77; died suddenly, Nov. 10, 1936, in Duluth, Wis.

**William H. Rieman**, Detroit; Detroit College of Medicine, 1893; member of the Michigan State Medical Society; aged 71; died, Nov. 3, 1936, of cerebral thrombosis and arteriosclerosis.

**Luther A. Parker**, Sault Ste. Marie, Tenn.; University of Tennessee Medical Department, Nashville, 1909; member of the Tennessee State Medical Association; aged 60; died, Sept. 25, 1936.

## PARIS

(From Our Regular Correspondent)

Dec. 15, 1936.

**The French Congress of Internal Medicine—The Parathyroid Syndromes**

At the twenty-fourth annual session of the French Congress of Internal Medicine the first topic was curable meningitis, as reported in *THE JOURNAL*, Dec. 12, 1936, page 1978. The second subject chosen for special reports and general discussion was the parathyroid syndromes. The first paper was by Professor Snapper of Amsterdam on the rôle of the parathyroids in bone pathology. He stated that renewed interest was due to three new facts: (1) that a generalized osteitis fibrosa (von Recklinghausen's disease) is accompanied by adenoma of the parathyroids, (2) that this invariably fatal disease is cured by removal of the tumor and (3) that this disease is characterized by definite clinical, radiologic and histologic signs and chiefly by a biochemical syndrome. Mandl of Vienna was the first (in 1926) to show that removal of the parathyroid adenoma was followed by cure of the bone disease. Whereas tetany due to hypofunction of the parathyroids is accompanied by decrease of the calcium and an increase of the phosphorus content of the blood, the reverse, i. e., a hypercalcemia and a hypophosphatemia, is true of von Recklinghausen's disease. The latter changes result in a generalized decalcification of the skeleton and deposits of calcareous material, in certain structures, the kidneys, lungs and gastric mucosa, excessive amounts of calcium phosphate being found in the urine, and as a result there is formation of renal calculi. Hence every case of the latter, especially when recurrent, should be examined as to the possible presence of a parathyroid adenoma. In addition to the formation of renal calculi, deposits of calcareous material in the form of infarcts in the renal tubules or as deposits in the intertubular tissue occur, both giving rise to such a degree of diminished renal function that uremia may follow, the patients being treated as nephritic unless there are evident skeletal symptoms. A typical case of this kind was cited in which biopsy of a bony tumor in the frontal region led to the suspicion of the presence of a parathyroid adenoma as the explanation of the hypercalcemia and uremic symptoms. Such an adenoma was found at operation and its removal was followed by a return to normal of the biochemical syndrome and disappearance of the symptoms of a severe chronic nephritis. Calcareous deposits may attain such enormous dimensions as to be demonstrable in roentgenograms. A case was also cited of recurrent giant-cell osteofibrotic tumors of the jaws. The blood chemistry was normal but there was marked hypercalciuria. The presence of a parathyroid adenoma was suspected and confirmed at operation. Following its removal, the maxillary cysts began to calcify.

The second paper in the symposium on parathyroid syndromes was by the physiologist Prof. Leon Binet of Paris and Dr. M. Henry of Lyons. Its title was "Tetany Parathyreopriva." An outline of our knowledge of postoperative tetany from the experimental and clinical standpoints was given. As to spontaneous tetany, there are three groups: (1) those in which the parathyroids bear no etiologic relation, (2) those in which there is a definite proof of this, and (3) cases in which the parathyroids as the underlying cause are still subject to discussion. In the last named group belong tetany as observed in pregnancy and in children and cases of associated idiocy and tetany. Clinically a "tetany thyreopriva" follows all the stages of the experimental form. Although the acute is the most common, the latent and chronic types are not rare. As to pathogenesis, various theories have been proposed, such as a hypocalcemia, a hyperphosphatemia, disturbances of the acid-base equilibrium and the toxic theory of Noël Paton and Findlay. All these are related to the metabolism of calcium. As to treatment in general, opotherapy has given the best results. In acute post-

operative tetany, complete isolation and sedatives are especially indicated. As to diet, large quantities of milk should be given. Meats and acids are to be prohibited. Intravenous and oral administration of calcium lactate and the injection from two to five times a day of from 10 to 20 units of parathyroid extract are the chief therapeutic remedies to be considered.

The third paper was by Coryn of Brussels on the influence of endocrines (parathyroids excluded) on bone diseases. All bone disorders due to endocrine dysfunction present three features in common: 1. The lesions are generalized, i. e., involve all bones. 2. They appear whenever there is an endocrine dysfunction. They can be reproduced by removal of the respective endocrine organ when there is hyperfunction and relieved by endocrine therapy when there is hypofunction. 3. When the hypofunction of an endocrine organ results in the appearance of a certain lesion, the hyperfunctioning of the same endocrine organ is followed by the appearance of the opposite lesion. As to the action of the individual endocrine organs, the eosinophil cells of the hypophysis exert their influence on the rhythm of cellular proliferation in bone tissue. When there is acceleration of the rhythm, gigantism results, and when there is retardation of rhythm, a dwarf. The action of the parathyroids had been taken up in the two preceding papers. The sex hormones act on cellular hypertrophy. The influence of the thyroid is very complex. The authors' own observations have shown that hypothyroidism retards cellular proliferation and hypertrophy, whereas hyperthyroidism does the opposite, thus acting like the hypophyseal hormone in causing respectively dwarfism and gigantism. Our knowledge of the action of the adrenals is still rudimentary.

In the discussion of these three papers, Jung of Strasbourg stated that in thirty cases of renal calculus an adenoma of the parathyroid was found to be the cause in three. Its removal in one case was successful. Scleroderma must be regarded as the cutaneous expression of a chronic hyperparathyroidism and removal of adenomas of the gland gave the best results. One encountered clinically cases of acute, subacute and chronic parathyroidism. The acute was represented by a generalized fibrocystic osteitis, the chronic by scleroderma. Jean Weill of Paris cited a case of tetany following radiotherapy for hyperthyroidism. With the exception of adenoma of the parathyroids, operations on these structures have no other indication. Lièvre directed attention to the fact that hypercalcemia in parathyroid adenoma is not constantly present. Certain cases develop without bone manifestation; e. g., the renal and cachectic forms.

**Closing of Houses of Prostitution**

Many foreigners who have visited France and especially Paris will be surprised to hear that Mr. Sellier, the present secretary of public health, proposes in the near future not only to close licensed houses of prostitution and to restrict occupancy of hotel rooms to those who have baggage but also to make the acquisition of syphilis a criminal offense and its treatment obligatory. In an article in the November 15 *Sidèle médicale* Dr. Léon Bizard protested against this policy of Mr. Sellier. Dr. Bizard is well qualified to discuss this question, being one of the staff of the St. Lazare Hospital, to which all prostitutes are obliged to go for the treatment of venereal diseases. There are 1,200 "tolerated" houses of prostitution in France and its colonies. The secretary of public health believes that syphilis can be conquered if the houses of prostitution are closed, that the white slave traffic will cease and that the landlords of the dens of vice will be ruined. Bizard remarks that this plan of freeing the people from sinful habits and leading them back to the path of virtue is a magnificent one but that there will soon be a rude awakening to the impossibility of the execution of such a plan. The innumerable hotels, according to the proposed law, will not be permitted to rent rooms to couples without baggage. Bizard

## Correspondence

### SYPHILIS IN BLOOD DONORS

*To the Editor:*—I was interested in reading the query of G. J. Potter, M.D., of Clewiston, Fla. (THE JOURNAL, Dec. 19, 1936, p. 2079) with reference to tests for syphilis in blood donors. Dr. Potter can overcome the urgency of an immediate Wassermann or Kahn test by doing as I did in this small town of Hemet a year and a half ago. I advertised in our local town sheet for donors to be examined so as to make up an eligible register of registered donors who wish to sell their blood when called on.

I arranged with a nearby laboratory, which was willing to do Wassermann-Kahn combination tests for \$1 each. I took and prepared separate histories of each donor in my spare time and did a complete blood count and blood sugar and blood grouping, keeping a record of these with the history. (The blood grouping serum I obtained from the Blood Transfusion Betterment Association, 39 East Seventy-Eighth Street, New York.) This sells for \$2 for twenty capillary tubes for each group and is very easy to do.

For an expenditure of \$14 I now have an eligible list of ten donors (one group I, two group II, two group III and five group IV) and ten tests left to test patients with who may require an emergency transfusion. Two transfusions since then have more than covered the expenditures made. I use and have ready sterilized outfits of both the direct and indirect methods of blood transfusion.

Then attached to or typewritten on the back of the history is the following, which the donor signs before a witness:

I, [name of donor], a registered donor, hereby agree to keep myself in good health and respond at once to call from the doctor (named above) or his agents, as a prospective blood donor when so called by them. Compensation for blood shall be at the rate of \$5 per hundred cubic centimeters for each 100 cc. or fraction thereof drawn from a donor. Compensation for responding to a call shall be paid only after blood is drawn from the donor selected. No fee shall be expected to be paid to me by any one for transportation coming to or leaving the hospital or for time in waiting to be selected, unless agreed to at the time I am being called on to present myself.

The donor further agrees that \$5 shall be deducted by Dr. Jesse Citron from my first fees as compensation for giving my blood. This reimbursement to Dr. Citron is to cover the expense to him for examination of me as a registered donor. This required fee shall be paid only once by the undersigned. (Painless surgical care and professional procedure will be exercised.)

Witnessed by..... Signed [name of donor.]

This method has gained for me the confidence of this mountainous community and removed from my consciousness the nightmare of fatality from hemorrhage. Professional security is denied to no community, no matter how small, that has a doctor who can focus a low power lens and draw blood for a Wassermann test.

JESSE CITRON, M.D., Hemet, Calif.

### REQUESTS FOR REPRINTS

*To the Editor:*—Word has gone about that the way to furnish one's medical library with the last word on any subject is to secure reprints of articles as they are published. As a result, many physicians are sending out printed postal card requests for reprints. In the last two or three years the appearance of an article by me has been followed promptly by a deluge of these card requests; but, while attention to one's writings would seem flattering, I note that when genuine interest is shown the request comes by letter enclosing postage. As I do not purchase enough reprints to meet all requests, I have learned to consign the postal cards to the waste basket. I wonder how other authors feel about it.

WALTER A. BASTRO, M.D., New York.

### VISUALIZATION OF AMOUNT OF RESIDUAL URINE

*To the Editor:*—In THE JOURNAL, Dec. 5, 1936, page 1886, there is an interesting and valuable account of visualization of the amount of residual urine, by Edwin Beer. This is a very important procedure. I was under the impression that it was quite generally known, as I have been using it for a number of years. The question of priority is quite unimportant. However, I should like to quote from chapter I, "Urologic Diagnosis," by Hager and Braasch, in Dean Lewis's Practice of Surgery, volume VIII, in which I state on page 68:

Excretory urography also affords a means of estimating the amount of bladder retention when it is not feasible or desirable to carry out retrograde study.

B. H. HAGER, M.D., Los Angeles.

### THE ILLINOIS OCCUPATIONAL DISEASE LAW

*To the Editor:*—Lately the state of Illinois has made effective a series of acts related to employment and providing for compensation and other benefits for occupational disease. In the occupational disease law (house bill 10, approved March 16, 1936), the heart of the provisions therein made is a definition of an occupational disease, which in part reads "A disease shall be deemed to arise out of the employment only if there is apparent to the rational mind, upon consideration of all the circumstances, a direct casual connection between the conditions under which the work is performed and the occupational disease." . . . The full definition, almost in its entirety, appears to use the language appearing long ago in the McNichols' case, Massachusetts 497, Northeastern Reports 697, which in turn is stated to have been derived from many old English cases. However, there is one egregious difference. In the McNichols' case, and presumably in the early English cases, the word "causal" and not "casual" is used. Thus "a direct causal connection" between the conditions under which work is performed and an occupational disease is of much different significance than "a direct casual connection." If the word "casual" is accepted as meaning "uncertain, precarious, superficial, occasional, incidental," it becomes manifest that such a relationship may be shown to exist between almost any disease that arises in an industrial worker and the conditions under which he works. Present day concepts of an appropriate definition of a true occupational disease contemplate a far more definite relationship between the disease state and work conditions as the source than that embodied in the term "casual," as ordinarily applied. It is assumed that the appearance of this word "casual" in the Illinois law represents an overlooked typographical error rather than intention. No less, the appearance of this word is mischievous.

Physicians called on for testimony or opinions connected with claims or trials for occupational disease inevitably will find themselves unable, in many instances, to deny a "casual" relationship between given work exposures and existing disease states in a worker, when on the other hand they may be fully convinced of the absence of a "causal" relationship. From the language of this Illinois law, the defending manufacturer almost with certainty will be unable to maintain a defense because of this liberal definition of an occupational disease.

It is not within my province to question the intent of the Illinois legislature or to anticipate the interpretation of the word "casual" that may be made by judicial bodies in that state or elsewhere. However, since the Illinois occupational disease law is the last to have appeared in this country, it is likely that other states now contemplating similar legislation are about to accept to a substantial degree the language and definition of this Illinois law. This may prove to be unfortunate, in fact, it is necessary to show only a "casual" connection between the

leads in turn to a paucity of country doctors. Many of the insured are thus forced to seek medical attention at the hospital, as even first aid treatment is not to be found elsewhere. A country physician may also hospitalize his more serious cases, as otherwise he would be forced to practice with a deficit. The fluctuation in the total expenditures of the sick insurance is shown in table 3. The administrative expenses of the sick insurance amounted in 1934 to around 135,000,000 marks, as against 162,300,000 marks in 1930 and 132,300,000 marks in 1932.

Further interesting data supplied by Dr. Hadrich in the *Deutsches Ärzteblatt* concern the number and distribution of the insurance physicians in the year 1936. Hadrich obtained

TABLE 3.—Total Expenditures of the Sick Insurance

Year	Disbursements in Millions of Reichsmarks
1929 .....	2,192
1930 .....	1,988
1931 .....	1,646
1932 .....	1,217
1933 .....	1,181
1934 .....	1,314
1935 .....	1,490

his figures from the authoritative League of Insurance Physicians of Germany. There were on July 1, 1936, 30,559 insurance physicians within the reich, compared with 32,620 in 1933. This means a decrease of 2,061 doctors despite the fact that in the same period the numbers of the insured were increased by about 2,000,000 persons. Four basic causes have contributed to this decline in the number of physicians: the drifting of insurance doctors into governmental health service, a similar drifting into the medical service of the defense forces, an increase in the number of positions as heads of institutions for the care of the sick, and the expulsion of non-Aryan physicians from insurance practice. Computation of the distribution of insurance physicians according to the several German provinces and so on shows that throughout the reich there is an average of 617 insured persons for each insurance physician (according to the licensing clause of the insurance practice law, one physician is allowed for each 600 insured). The proportion of the insurance physicians to the insured is greater in some provinces, smaller in others, least in Upper Bavaria (427), greatest in the Saxon industrial region of Chemnitz-Zwickau (1,032). Of the 30,559 insurance physicians, nearly 21,000 are general practitioners; 9,600 are specialists. On the average there are five specialists licensed for insurance practice to every 10,000 insured persons. Alongside the number of insured must be reckoned from 8,000 to 10,000 members of the families of the insured who are eligible for benefits, and there are also those uninsured persons who consult the specialist as private patients. In general the number of specialists is not excessively great. It ought certainly in many districts, as in Berlin and Hamburg, for example, not to show any further increase. In many such communities the proportion of specialists is in excess of 40 per cent of all insurance physicians. Nevertheless, according to the estimates of the insurance physicians themselves this proportion ought never to be exceeded.

Of these 9,600 specialists, 1,397 limited their practice to dermatology and venereology; these fields have the strongest numerical representation, yet the number of specialists in them undergoes a constant decline. The second largest group is that of the otorhinolaryngologists with 1,330 physicians; next follow 1,216 surgeons, 1,291 gynecologists, 1,185 internists and 1,119 ophthalmologists. It is also assumed that the number of gynecologists and internists must decrease, albeit more slowly. At a greater distance there follow next 680 pediatricians, 468 neurologists and psychiatrists, 253 orthopedists, 188 roentgenologists (the number of insurance physicians specializ-

ing in this field is on the increase), 175 phthisiologists and other specialists in respiratory diseases, 143 gastrologists and 121 urologists (a group believed to be rather on the increase because of the greater aging of the German population); lastly there are eighteen stomatologists and specialists in maxillary disorders as well as sixteen serologists, bacteriologists and so on.

#### News of the Student Bodies

Heretofore, substantial data on the monthly income or allowance of university students have not been available. Yet previous attempts at compilation of such data have demonstrated that a relatively large number of students were without sufficient means to finance a university career and that the financial needs of the indigent students were about ten times in excess of the available resources of the national student aid organization. This reichsstudentenwerk was originally founded by the students themselves in order to help the needy among them earn a little money at odd jobs while at the university. To collect more data on student needs, the studentenwerk at the University of Erlangen undertook in the winter semester of 1935-1936 an investigation of the monthly allowances received by students. Some 825 of the approximate 1,400 students formed the material of the survey. These were divided into those who received money from parents at home and those who were compelled to work their way through. After deduction had been made for the academic tuition fees, the figures of actual monthly income for living expenses given in table 4 were arrived at. The rest of the students received still higher monthly allowances. According to these figures about 53 per cent of the students received less than 80 marks, the amount set as minimal by the reichsstudentenwerk. Of those students who received funds from their parents, 62 per cent were allowed less than 50 marks per month. It may be said that the majority of German students live in penury.

The reichsstudentenwerk was able to dispense, through its local organization at Erlangen, a total of some 360,000 marks to needy students during the summer semester of 1935. Altogether 6.6 per cent of the total student body could at that time be rendered some slight financial assistance and, if other types of aid are included, the proportion of students aided was 9.6 per cent (7,383 students) compared to 7.8 per cent aided during the summer semester of 1934. The amount advanced per individual student was 70.75 marks, as against 68.50 marks in the summer semester of 1934.

TABLE 4.—Monthly Income of Students for Living Expenses

Percentage of Student Body	Monthly Income for Living Expenses
16 .....	less than 50 marks
26 .....	50-70 marks
25 .....	70-90 marks
25 .....	90-130 marks

At Heidelberg in August there assembled fifty students of natural science from the corresponding section of the National Socialist German Studentenbund for the purpose of establishing a "natural science camp" in the vicinity. At the hoisting of the colors the group director pronounced the following watchword: "The Aryan natural scientific research of today shall be the technic of tomorrow."

According to a regulation just issued, only those students who are members of the National Socialist party will be allowed to matriculate at the University of Berlin in the winter semester 1936-1937. This measure owes its origin to the idea that, in view of the political preeminence of the national capital, permission to study at Berlin University should be considered a special privilege and that this privilege belongs first of all to those students who have served the National Socialist movement.

the chief fuel for Diesel engines is a fairly well purified petroleum fraction of almost constant consistency.

In a publication by Maleev entitled "Safety and Diesels" (*Power* 78:142 [March] 1934) no mention is made of this kind of accident in connection with Diesel engine operation. The service department of the Electro-Motive Corporation is said to have issued a bulletin to its service engineers in which it warns against the fuel spray from the tip of a unit injector. This spray has sufficient penetrating power to puncture flesh and destroy tissue. So far as is known there is no published accumulated experience in this domain and no established treatment. If the author of this query is seeing considerable numbers of this type of case, he himself should develop this scientific material for the purpose of publication for the guidance of others.

#### TREATMENT OF VITILIGO

To the Editor:—For the past two months I have been treating a patient suffering from leukoderma of the right foot. It started as a small whitish spot on one of the toes, and for the last two months it has grown to so great an extent as to involve almost one third of the whole skin of the right foot. The prescriptions I have been giving are the following:

R. Solution of potassium arsenite..... 10 cc.  
Sig.: Three drops three times a day in increasing doses.

R. Essence of bergamot ..... 2.50 cc.  
Alcohol ..... ad 50 cc.

M. Sig.: To be applied externally as directed every morning.

R. Alcohol  
Ether ..... aa 50 cc.

M. Sig.: To be applied at night.

At the same time the foot was exposed to ultraviolet rays for five minutes in increasing doses every other day. With this treatment there is no noticeable improvement. Recently I was told to use gold sodium thiosulfate intravenously, starting with 1 mg. and gradually increasing it up to 0.01 Gm. On the other hand, I was told by another physician that it is not safe to use gold sodium thiosulfate. Having no experience as yet with the medicine until now, I have not used it. May I know your treatment of the case? Please omit name.

M.D., Cavite, P. I.

ANSWER.—In the past it has been held by most dermatologists that there is no hope of improving vitiligo by treatment, and they have advised painting the white spots with the juice of walnut husks or some other dye to conceal them. A solution of potassium permanganate of the proper strength can be used for this purpose. The job must be done skilfully, whatever the pigment used. Others have recommended bleaching the hyperpigmented border of the vitiligo patch with a solution of mercury bichloride painted on several times a day until exfoliation occurs.

Buschke in 1907 reported failure in the treatment of vitiligo spots with ultraviolet rays. He could not get an even pigmentation in this way. Stein later reported that, although the pigment formed was real melanin, it was not permanent. Encouraging results are reported from long continued use of ultraviolet rays. Many of the spots fill in gradually and finally disappear. Others resist the action of the light.

Nadel (Ein Beitrag zur Behandlung der Vitiligo, *Acta dermat. venercol.* 11:141 [April] 1930) gave acriflavine hydrochloride by mouth, 0.1 Gm. once a day, and sun baths or treatment with ultraviolet rays twice a week. In a patient who had had vitiligo for ten years the result was good, the patches which were most recent being apparently most responsive to treatment. His second case was entirely unrelieved. The white patches were at sites of pressure of the belt over the iliac crests. The third case also yielded promptly to the combined use of acriflavine hydrochloride or similar light sensitizing drug, followed by ultraviolet treatment.

Freund of Trieste, who first reported berlock dermatitis in 1916, tried the production of it on the depigmented spots of vitiligo. The difficulty is that only certain skins produce pigment in response to the application of oil of bergamot followed by sunlight or ultraviolet rays. Others do not show any effect from the oil applications and it has been reported that the use of oil of bergamot in this manner may cause dermatitis. Gross and Robinson (Berlock Dermatitis, *Arch. Dermat. & Syph.* 21:637 [April] 1930) even saw the application of the oil protect the skin from the action of light, and they quote Szanto as having seen the same effect. The usefulness of the application of a bergamot oil solution followed by light is thus strictly limited to those sensitized to the oil.

Lindsay in 1929 reported the cure of vitiligo by intravenous injections of gold sodium thiosulfate (Treatment of Vitiligo with Gold Sodium Thiosulfate, *Arch. Dermat. & Syph.* 20:22 [July] 1929). Since then this method of treatment has been used in many cases, with gratifying success in a few. If used, precautions should be taken as in the use of the arsenamines. Cardiac, pulmonary, liver or kidney disease of any extent or

severity precludes the use of the method. Before each treatment the urine should be examined for albumin and casts and the patient questioned about any gastro-intestinal or skin symptoms following the preceding treatment. The dosage of gold sodium thiosulfate ranges from 5 to 100 mg. and the course consists of from ten to twenty doses, given once a week. Skin or kidney reactions indicate interruption of the course of injections. Febrile or gastro-intestinal reactions may be of less import, but their meaning must be carefully evaluated.

Cohen, in the case of a young woman whom he treated by intravenous gold sodium thiosulfate, used a 10 per cent solution of oil of bergamot in alcohol on the spots on the face, followed by ultraviolet exposures. The face cleared and the spots on the abdomen and thighs improved, though they received no ultraviolet treatment. A year after treatment was ended there had been no recurrence (Successful Treatment of Vitiligo, *Arch. Dermat. & Syph.* 28:215 [Aug.] 1933).

In the case under consideration, it would be advisable to try ultraviolet treatments or sun baths in graduated doses for some time. If the results are not satisfactory, one of the other methods could be added.

#### ACTINOMYCOSIS

To the Editor:—A white man, aged 35, in 1930 immediately following a dental extraction, had an acute swelling, with pain, in his face and jaw on the affected side. A few months later this had progressed to a point of localized pus formation, and since that time numerous, usually superficial, abscesses have been opened and drained. Repeated examinations of pus have failed to demonstrate organisms other than the usual pyogenic ones. About two years ago at the Mayo Clinic a diagnosis of actinomycosis was made and x-ray treatment was instituted together with a continuation of large doses of iodine, which he had been taking off and on since soon after the onset. Considerable improvement in the local condition ensued but even to the present time there are occasional superficial abscesses there. Repeated x-ray examinations of this region fail to demonstrate pathologic changes other than evidences of superficial periosteal involvement. Eighteen months ago, with an acute onset, he developed what was apparently an ordinary lobar pneumonia involving the right lower lobe, running an average course and subsiding by 4½. About two weeks later, when convalescence was apparently well established, there was a recrudescence of fever, pleuritic pain, and so on, in the involved lung area. X-ray examination failed to show the anticipated empyema but did show "dulness extending out from the hilus, sharply outlined and suggesting mediastinal involvement rather than lung infection, with possibly a small amount of free pleural fluid." In view of this history, actinomycosis in his jaw, this was considered as probably actinomycotic, and he was given several series of high voltage roentgen therapy together with the other usual measures. Since that time there have been daily rises of temperature of 1 or 2 degrees, occasionally higher. There has been more or less pain in various regions of the right side of the chest, weakness and slight coughing. He was kept at rest several months with some improvement. For the past several months he has attended to part of his duties, mostly office work, and seems to get along about as well with this activity as when he stayed in bed. In fact, his temperature record shows that over the week end and at other times when he stays constantly in bed it is almost invariably higher than on the days when he is up and around. About three months ago there developed several abscesses, apparently arising over the ribs of the anterior right chest. These were open and have remained as draining sinuses. Repeated examinations of the pus from these and the sputum have failed to demonstrate Actinomyces. Several months ago he developed a pain in the lower dorsal spine region; x-ray examination showing a destructive process involving the eleventh dorsal vertebra, and a plaster jacket was applied with him suspended in head traction, with considerable comfort. X-ray examinations of the lungs at intervals show little change in the lung condition. Throughout all this time the patient's general condition has on the whole remained very good; in fact, he has appeared to be in much better general health than one would expect. Lately, however, he has been losing weight and there is a progressive anemia as a result of mild leukocytosis. Other routine laboratory work gives results within normal limits. The radiologists appear reluctant to administer further x-ray therapy, feeling that it will not be helpful and may possibly be harmful. If this is published, please omit name. M.D., Albany

ANSWER.—In the case cited the chain of events and the sequence of symptoms apparently represent extension of the actinomycotic process to the mediastinum and respiratory apparatus and apparently also to the lumbar spine. Although this would be decidedly unusual, the extension may have taken place through the lymphatic tracts, and this may account for the rather slow development of lesions in the different parts. With such extensive disease it is not likely that any method of treatment can result in cure. Nevertheless, radiotherapy directed to the mediastinal structures through two anterior and two posterior fields (moderate total dose of about 4000 r for the anterior fields and also directed to the lower dorsal part of an erythema dose) and also directed to the lumbar part of the spine through at least two posterior fields with the rays converging on the spine, and with a smaller dose per field, might improve the patient's condition considerably.

## Deaths

**Arthur Stern** \* Elizabeth, N. J.; Ludwig-Maximilians-Universität, Medizinische Fakultät, München, Bavaria, Germany, 1891; member of the American Academy of Pediatrics; fellow of the American College of Physicians; formerly member of the board of health; on the staffs of the Elizabeth General, St. Elizabeth and Alexian Brothers' hospitals, Rahway (N. J.) Memorial Hospital and the Somerset Hospital, Somerville; in 1933 delegate to the third International Pediatric Congress in London; aged 68; died suddenly, Nov. 28, 1936, of coronary occlusion.

**Hugh C. Russell** \* Milwaukee; Milwaukee Medical College, 1907; also a graduate in pharmacy; formerly associate professor and professor of pharmacology and dean at the College of Pharmacy, Marquette University; at one time professor of pharmacology at the Dental School, Marquette University; served during the World War; member of the staff of the Marquette University Hospital and since 1929 member of the staff of the Milwaukee Hospital; aged 61; died, Nov. 29, 1936, of cerebral hemorrhage.

**Frank Austin Swartwout**, Washington, D. C.; Howard University College of Medicine, Washington, 1893; Southern Homeopathic Medical College, Baltimore, 1894; member of the board of directors and past president of the American Institute of Homeopathy; on the staff of the National Homeopathic Hospital; aged 69; died, Dec. 16, 1936, of heart disease.

**Thomas George Odell**, Boulder City, Nev.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the Nevada State Medical Association; veteran of the Spanish-American and World Wars; aged 63; died, Nov. 9, 1936, in a hospital at Santa Monica, Calif., of pulmonary tuberculosis and chronic myocarditis.

**Arthur G. Meserve**, Robinson, Ill.; Miami Medical College, Cincinnati, 1874; member of the Illinois State Medical Society; past president of the Crawford County Medical Society; for many years a member of the school board and board of health; aged 82; died, Nov. 14, 1936, of cerebral hemorrhage and chronic myocarditis.

**George Warren Gardner**, Providence, R. I.; Harvard University Medical School, Boston, 1900; fellow of the American College of Surgeons; served during the World War; for many years on the staff of the Rhode Island Hospital; aged 64; died, Nov. 14, 1936, in Damariscotta, Me., of arteriosclerosis and cerebral hemorrhage.

**James Avery Finger** \* Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1910; assistant professor of medicine at his alma mater; for many years visiting physician to the Roper Hospital; aged 53; died, Nov. 23, 1936, of cerebral thrombosis following an operation for nephrolithiasis.

**William Joseph Happel**, Nazareth, Pa.; Jefferson Medical College of Philadelphia, 1919; member of the Medical Society of the State of Pennsylvania; president of the Northampton County Medical Society; on the staff of the Easton (Pa.) Hospital; aged 43; died suddenly, Nov. 29, 1936, of cerebral hemorrhage.

**Emsley Thomas Johnson** \* Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1921; president-elect of the Jackson County Medical Society; instructor in pathology at his alma mater; pathologist to St. Joseph Hospital; aged 44; died, Nov. 21, 1936, of cerebral hemorrhage.

**John De Witt Hawks**, East Lansing, Mich.; Rush Medical College, Chicago, 1891; formerly associate professor of electrophysiology and roentgenology, Hahnemann Medical College and Hospital, Chicago; at one time on the staff of the Hahnemann Hospital, Chicago; aged 68; died, Nov. 19, 1936.

**James M. Beveridge** \* Oregon, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; past president of the Ogle County Medical Society; chairman of the county exemption board during the World War; aged 68; died, Nov. 21, 1936.

**John Walter Goodheart**, Bellingham, Wash.; Chicago Medical College, 1890; fellow of the American College of Surgeons; member of the staff, St. Joseph's and St. Luke's hospitals; district surgeon to the Chicago, Milwaukee, St. Paul and Pacific Railroad; aged 70; died, Nov. 28, 1936.

**Willard Parker Green** \* Minneapolis; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; senior epidemiologist of the state board of health;

aged 65; died, Nov. 26, 1936, in the University Hospital, of a skull fracture received in a fall down the stairs.

**Hugo Francis Mehl**, Milwaukee; University of Pennsylvania Department of Medicine, Philadelphia, 1902; for many years school physician for the city health department; was a medical examiner for a number of life insurance companies; aged 60; died, Nov. 1, 1936, of hepatic cirrhosis.

**Thomas Francis McKenna**, Syracuse, N. Y.; Bellevue Hospital Medical College, New York, 1891; for many years examiner for the Metropolitan Life Insurance Company; member of the staff of the Crouse-Irving Hospital; aged 71; died suddenly, Nov. 3, 1936, of cerebral hemorrhage.

**Winfred Eugene Baldwin**, Montclair, N. J.; Bellevue Hospital Medical College, New York, 1891; author of "Advanced Lessons in Physiology"; aged 71; died, Nov. 29, 1936, in St. Vincent's Hospital, of adenoma of the prostate, diabetes mellitus and cerebral hemorrhage.

**Solomon Jay Ulman**, Salt Lake City; University of Maryland School of Medicine, Baltimore, 1889; member of the Medical and Chirurgical Faculty of Maryland; served during the World War; aged 69; died, Nov. 12, 1936, of chronic myocarditis, nephritis and arteriosclerosis.

**Harry Denton Stryker**, Reading, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; for many years on the staff of St. Joseph's Hospital; aged 66; died, Nov. 17, 1936, of coronary sclerosis.

**Berthold A. Williams** \* Cincinnati; Medical College of Ohio, Cincinnati, 1885; member of the American Psychiatric Association; on the staff of the Longview State Hospital; aged 74; died, Nov. 18, 1936, in the Christ Hospital of a ruptured gastric ulcer.

**Louis G. Harney**, East St. Louis, Ill.; Northwestern University Medical School, Chicago, 1903; member of the Illinois State Medical Society; served during the World War; member of the staff of St. Mary's Hospital; aged 57; died, Nov. 16, 1936, of heart disease.

**William De Witt Stewart**, Spencer, W. Va.; University of Maryland School of Medicine, Baltimore, 1896; member of the American Psychiatric Association; aged 62; on the staff of the Spencer State Hospital, where he died, Nov. 2, 1936, of bronchopneumonia.

**Edwin Fox Todhunter**, Washington C. H., Ohio; Starling Medical College, Columbus, 1900; member of the Ohio State Medical Association; president of the Fayette County Medical Society; served during the World War; aged 64; died, Nov. 15, 1936.

**Louisa Hemken** \* Los Angeles; Rush Medical College, Chicago, 1929; instructor in pathology, University of Southern California School of Medicine; formerly on the staff of the San Bernardino (Calif.) General Hospital; aged 32; died in November 1936.

**Gaines Levy Brightwell**, Leedey, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1931; member of the Oklahoma State Medical Association; aged 29; was killed, Nov. 22, 1936, when his car went over an embankment near Beaver.

**John Henry O'Connor** \* New York; University of the City of New York Medical Department, 1891; for many years a member of the national guard of New York; on the staff of the Bellevue Hospital; aged 67; died, Nov. 17, 1936, of pneumonia.

**N. Lewis Bosworth**, Lexington, Ky.; University of Louisville (Ky.) Medical Department, 1892; member of the Kentucky State Medical Association; for many years member of the city board of health; aged 67; died, Nov. 20, 1936, of coronary occlusion.

**Edward S. Lester**, Chatham, Va.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; instructor at the Hargrave Military Academy; aged 61; died, Nov. 14, 1936, in the Memorial Hospital, Danville, of hypertension and myocarditis.

**Joseph A. Jones**, Corsicana, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1898; member of the State Medical Association of Texas; aged 65; died, Nov. 11, 1936, in a hospital at Dallas of Ludwig's angina.

**Frank Adams Bowden**, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1902; aged 60; died, Nov. 14, 1936, in the Fairview Park Hospital, of cerebral embolus following a prostatectomy.

## COMPLICATIONS OF PERNICIOUS ANEMIA

*To the Editor:*—I have a patient with pernicious anemia who presents several peculiar features. She requires twice the recommended dosage of liver and iron to keep her cell count and hemoglobin nearly normal. She is getting good preparations: Lederle's concentrated solution liver extract intramuscularly three times weekly, and from twelve to eighteen 7½ grain (0.5 Gm.) capsules of iron and ammonium citrate daily. She is getting thirty drops of dilute hydrochloric acid with each meal. She also has one capsule of percomorph oil and a little brewers' yeast daily. With all this medication it is possible only to keep her red count between 4,300,000 and 4,800,000 and hemoglobin between 75 and 90. Even though she is getting plenty of hydrochloric acid, the urine tests alkaline part of the time. There is no microscopic pus or bacteria in the urine. About twice weekly she loses her balance and falls weakly forward and to the right. She says that she feels this loss of balance first but cannot move her legs quickly enough to keep from falling. There is no vertigo. Have you any suggestions? CARL H. GRAF, M.D., Boulder, Colo.

**ANSWER.**—On rare occasions one encounters a patient with pernicious anemia who requires an unusual intake of liver substance for maintenance purposes. In such patients one will find some complicating pathologic condition. The teeth, tonsils, sinuses, gallbladder and genito-urinary tract must be carefully considered to rule out infection. Myxedema, associated with a macrocytic anemia, may be mistaken for pernicious anemia or may occur in conjunction with it. Hypertension, generalized arteriosclerosis, a malignant condition with hemorrhage and unusual psychic disturbances may each act as a complication resulting in a need for a greater than usual intake of antianemic substance.

In a patient with such extreme resistance as that described, especially if associated with neural disturbances, it is important to rule out multiple sclerosis and a tumor causing pressure on the spinal cord. The former is often associated with some degree of anemia which is hypochromic in nature, whereas the latter may occur as a metastatic lesion from a primary malignant growth involving the gastro-intestinal tract. Under these circumstances an anemia may be present which will vary in its characteristics depending on the acuteness and severity of the resulting hemorrhage. Although the data are not sufficient to allow a positive diagnosis to be made, it seems likely that this patient has multiple sclerosis.

## TREATMENT OF SYPHILIS

*To the Editor:*—A physically well built man, aged 24, gives a history of exposure on February 16 and March 8, developing a soft chancre where the frenulum joins the glans on about March 20. A Wassermann test March 26 was negative, but one taken April 9 was 3 plus positive both for it and the Kahn test. In the meantime, around April 17 the chancre was healed following the application of an ointment (which was probably a mercurial). There is a previous gonorrheal history. The patient has now come to me for treatment and I have outlined the following for him: twenty weekly injections of nearsphenamine of 0.6 Gm.; ten injections of aqueous bismuth sodium tartrate at weekly intervals starting with the eleventh week of treatment (gluteal); a blood drawn in the twenty-first week, which if positive will demand another course exactly as before. Is this adequate treatment for a case that apparently is about ten weeks old? If not, what further treatment should be used? Can I assure the patient of anything approaching a cure after the first course (if the blood is negative and stays negative); after the second course should the first be followed by a positive blood? I have further advised that, should he get a negative blood result after the first course, examinations should be repeated at intervals of three months for three years and thereafter at intervals of six months. Any positive one should be repeated and if again positive be followed by another routine such as outlined. The only abnormalities in this case are palpable tender inguinal glands (which he says are receding in prominence), a backache, and the scar replacing the chancre (?). Of what value is water soluble potassium bismuth tartrate and, if of any value, when should it be given and in what kind of dosage? (I speak here of oral administration.) Please omit name. M.D., Ohio.

**ANSWER.**—Before treatment is started the diagnosis of early syphilis should be verified by means of a repeat serologic test or by the appearance of secondary syphilis.

The treatment outline suggested, i. e., twenty weekly injections of nearsphenamine, the last ten of which are accompanied by aqueous bismuth with treatment presumably to be stopped if the blood Wassermann reaction at the end of this time is negative, is wholly inadequate. It is inadvisable to give as many as twenty consecutive injections of an arsphenamine product in early syphilis. The treatment procedure adopted should be that outlined by the Cooperative Clinical Group (Stokes, J. H., and others: *Standard Treatment Procedure in Early Syphilis*, THE JOURNAL, April 21, 1934, p. 1271). This treatment system involves the alternating use of courses of an arsphenamine with courses of an insoluble or liposoluble bi-muth product, carried on for a minimum of sixty-nine weeks without rest periods of any kind.

Treatment should never be stopped in early syphilis if the blood Wassermann reaction is reduced to negative at the end of the first course. It must be continued for an arbitrary minimum of approximately eighteen months, regardless of serologic response. The obtaining of a negative blood Wassermann reaction early in the course of treatment has nothing whatever to do with "cure."

The oral administration of water soluble potassium bismuth tartrate or of any other bismuth preparation has as yet no place in the treatment of any form of syphilis and particularly in the treatment of early syphilis. This method is wholly in the experimental stage and has not yet been proved to be of value either in experimental animals or in human beings.

## SIGNIFICANCE OF LIGHT FLASHES

*To the Editor:*—Miss C., aged 42, whose previous health had been good, had for two years daily and frequent flashes of light, always with an upward direction, of the size and shape of a jelly-bean, of moderate brightness to intensive and distressing; they flashed upward, singly or in strings like balloons, varying in color from orange in the morning to bluish white at night. One brother was blind from glaucoma; the other had night-blindness; a sister had retinoblastoma. An ophthalmologist reported that during February, March and April 1935 the tension in each eye was from 40 to 70 by a McLean tonometer and advised immediate operation. Pilocarpine was used without relief. She saw her former ophthalmologist in another state, who reported on April 29, 1935, that the optic disks showed a simple physiologic cupping large and extending beyond the center, but no different than eleven years before; no halos; no contractions of the fields; no diminution of vision, and tension 24 and 26 by Schiötz. He advised omitting pilocarpine and no operation. On May 18, 1936, I found the tension in each eye 24 by the Gradle-Schiötz tonometer. The patient had not used pilocarpine or any eye drops for a year. The flashes have continued. The pupils are not dilated; the eyeballs are white. Can the reason for the very disturbing flashes be explained? Can they be relieved? Please omit name.

M.D., Massachusetts.

**ANSWER.**—The entopic phenomena of light flashes such as are described here are difficult to explain. They may occur in a perfectly normal eye or they may occur as the forerunner of some retinal condition. In all probability they are due to unexplained electric currents within the retina itself. The perception of such phenomena is exaggerated by a general hypersensitivity of the patient, particularly the hyperthyroid type, and in some cases may be lessened by the use of mild sedatives. Such entopic phenomena are not necessarily associated with any form of glaucoma.

## EFFECTS OF VASECTOMY ON SEX ACTIVITY

*To the Editor:*—In doing a vasectomy under local anesthesia on a young adult is there any danger entailed as far as the ultimate effect on sexual activity? I refer to the removal of say 1 cm. of the vas on both sides down in the scrotum. Does any atrophy of the testicle follow this and is there any disturbance of the sexual function? Please omit name and address.

M.D., Iowa.

**ANSWER.**—Removal of a portion of the vas should not be followed by atrophy of the testicle or any disturbance in function. In fact, the contrary is usually noted following such an operation if correctly done. The complications that have taken place following this operation usually have been due to technical error in carrying out the operation. If the blood vessels of the cord are included in the excision or ligation, disturbance of the vascular supply to the testicle, with consequent atrophy and reduced function may result. There is no need for this to happen, however, provided the vas is freed and is excised separately, without disturbance of the vascular supply. The incision should be made over that portion of the vas situated a short distance below and lateral to the base of the penis. The vas is much easier to find and to isolate in this area than in the portion nearer the testicle.

## COMPARATIVE ACTION OF SEDATIVES

*To the Editor:*—Can you give the comparative sedative action of sodium bromide versus chloral hydrate, grain for grain? In a solution containing sodium bromide (15 grains) and chloral hydrate (5 grains), which of the doses would you consider the more potent sedative? Please omit name.

M.D., New York.

**ANSWER.**—There is no such way of comparing bromide and chloral as "grain for grain," the two act so differently. The relation of the U. S. P. average dose of 1 Gm. of sodium bromide to 0.6 Gm. of chloral hydrate does not represent the true condition. Chloral is a specific nerve sedative, while bromide accumulation in nerve tissue and can easily reach a sedative when given in an overdose. The relation is 1 to 100.

**Henry M. Childress**, Glasgow, Ky.; Tennessee Medical College, Knoxville, 1898; aged 66; died, Nov. 1, 1936, at the home of his nephew near Dry Fork, of cerebral hemorrhage.

**Andrew Arnett**, Hurdland, Mo.; Missouri Medical College, St. Louis, 1882; aged 82; died, Oct. 23, 1936.

**James Campbell**, Tottenham, Ont., Canada; Trinity Medical College, Toronto, 1888; died, Nov. 2, 1936.

Medical Examinations and Licensure

COMING EXAMINATIONS  
STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, January 9, page 141.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Feb. 9-11, May 10-12, June 21-23, and Sept. 13-15. *Part III.* Chicago, Jan. 19-21. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants will be held in various cities throughout the country on April 17. Oral examinations for Group A and B applicants will be held in Philadelphia, June 7-8.* Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination will be held simultaneously in different centers of the United States and Canada in March. Practical examination will be given in St. Louis in April and at Philadelphia in June.* Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B applicants will be held in various cities throughout the United States and Canada, March 6. Practical, oral and clinical examinations for Group A and B applicants will be held at Atlantic City, N. J., June 7-8. Applications must be received at least sixty days prior to the examination dates.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Los Angeles, Jan. 23. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Chicago, March 26-27. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit, Michigan.

AMERICAN BOARD OF PEDIATRICS: New York, Jan. 23, and Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklin, Mayo Clinic, Rochester, Minn.

Pennsylvania July Examination

Mr. James A. Newpher, secretary, Pennsylvania State Board of Medical Education and Licensure, reports the examination held in Philadelphia and Pittsburgh, July 7-11, 1936. An average of 75 per cent was required to pass. Five hundred candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Coulege of Physicians and Surgeons of San Francisco.....	1	(1905)	1

Book Notices

*Principles of Biochemistry.* By Albert P. Mathews, Andrew Carnegie Professor of Biochemistry, University of Cincinnati, Cincinnati, Ohio. Cloth. Price, \$1.50. Pp. 512, with 5 illustrations. Baltimore: William Wood & Company, 1936.

This has been a standard textbook in physiologic chemistry with medical students and physicians for many years. The present edition is a completely revised and new work. It is the author's expressed purpose to adapt it for use in teaching biochemistry to medical students. Accordingly, the material is condensed and concisely presented. References have been purposely omitted because it is the author's opinion that the student does not have sufficient time to consult the current literature. The plan of organization differs from the conventional method of presenting the subject to medical students. Instead of taking up the chemistry of carbohydrates, fats and proteins, their digestion and absorption, the intermediary metabolism of these substances, and finally the end products of metabolism, the author has chosen to take up carbohydrates, fats and proteins and discuss them completely. The first three parts of the book deal with their chemistry and metabolism. Then follow sections devoted to a consideration of the special chemistry of blood, cartilage and bone, catalytic agents of growth and development (vitamins and hormones), and energy metabolism. This type of organization seems rational for one who has some knowledge of biochemistry and physiology, but many will question its adaptability for teaching medical students early in their medical education. It is an interesting deviation from conventional teaching of the subject, and the result of this method of instruction should make interesting pedagogy. It is evident from the organization of the book that the author has been painstaking in the selection and presentation of his data and that he had a definite teaching goal in view. As with most first editions, the book contains discussion which could

ing conditions and disease states. Certainly the proper functioning of physicians as witnesses may be thoroughly hampered in many respects if such should be the case. It seems reasonable to accept the requirement that a "causal" rather than "casual" relationship must exist before any disease state in a worker may be attributed to work conditions as the direct etiologic factor.

CAREY P. McCORD, M.D., Detroit.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### ANGINA PECTORIS

*To the Editor:*—A woman, aged 48, with normal blood pressure, in excellent health, was involved in an automobile accident, being thrown forward and backward, subjected to considerable fright, and sustaining a severe sacro-iliac strain. On arriving home two hours afterward she complained of pain in the region of the heart. She was immediately put to bed, where she stayed for approximately six months. On the third day she became depressed and emotional, became hysterical, and would cry over the most trivial matters. She gradually developed numerous hysterical and emotional attacks of pain in the region of the heart, which were diagnosed as nervous angina. During an attack of pain she did not remain speechless as in a true angina. These attacks increased in number until she had as many as twenty or thirty in twenty-four hours, most of which occurred during the night. The pain was not paroxysmal but dull and heavy, sometimes radiating to the left arm, and passing away slowly. A cardiologist found the heart normal in size, rather rapid, with no definite murmurs and no irregularity. The electrocardiogram was practically negative as to showing any disease of the coronary arteries or heart muscle, and a diagnosis of functional or nervous angina was made. Complete rest was advised, but in spite of this the attacks increased considerably in number, became greater in severity, and were relieved by the oral administration of glyceryl trinitrate, in my opinion an indication that a true angina was developing. Approximately six months after the accident she had one severe attack of angina pectoris that was not relieved by glyceryl trinitrate. All symptoms indicated a coronary thrombosis. Every possible thing was done to save her, but she died within seven hours. The patient, who up until the time of this accident was in excellent health, could run a considerable distance, play golf, dance, swim, climb mountains, and undergo any physical exertion without any discomfort, was immediately confined to bed and developed symptoms of a nervous angina. Did this patient have a preexisting disease of the coronary arteries? Were the symptoms of angina directly caused by the fright and injury? If there had been a disease of the coronary arteries prior to the accident, why weren't there any symptoms? Why do some of these patients have symptoms of angina and why do some of them with precisely similar lesions have none? There is no doubt that attacks can be precipitated in emotional and nervously sensitive persons by physical stress or anxiety; therefore, in my opinion, if it is possible for this patient, entirely free from symptoms, immediately to become bedridden for about six months and be incapable of doing anything requiring the slightest exertion for that period, there can be instances of angina apparently authentic in every way, which do not show coronary disease and in which a great number of functional or nervous attacks of angina can do damage to the coronary arteries which did not previously exist and ultimately cause a coronary thrombosis. Please omit name.

M.D., Massachusetts.

**ANSWER.**—This case serves to keep alive the controversy that has been going on since shortly after Heberden labeled the symptom complex now known as angina pectoris. The controversy is between those who adhere to the vasospastic theory of angina and those who insist that angina must be caused by organic coronary changes. As no necropsy report is given here it is possible to make out a fairly good case for either side.

First, it must be pointed out that coronary changes are found by the pathologist in almost all persons over 40 years of age. With this in mind, let us now discuss the case from the point of view of the adherents to the vasospastic theory of angina pectoris.

It is well known that angina pectoris may occur in persons who have no illness inconsistent with age demonstrable in the coronary arteries. This has been shown in fatal cases of angina pectoris that have come to necropsy. This fact has lent a great deal of weight to the theory that active vasoconstriction of the coronaries may be a cause of angina pectoris. This spasm of the coronaries is not the only cause, nor perhaps is it the most frequent cause, but it is conceivable that it may operate in the absence of all other causes.

Deaths from angina pectoris of this type will leave no pathologic evidence in the heart. It has been assumed that ventricular fibrillation results from the profound ischemia during the attack.

Coronary occlusion has been demonstrated in hearts with minimal coronary changes. On the same grounds it has been assumed that coronary spasm may be sufficiently severe to allow thrombosis to occur.

If these premises are accepted as tenable, it must be admitted that angina pectoris may occur in persons whose coronaries show no pathologic changes inconsistent with age and in whom physical and electrocardiographic examination will reveal nothing. It is unwise, however, to call this condition "functional angina." The word functional implies an innocuousness that does not exist here. There is an actual and considerable, sometimes almost total, reduction in the coronary circulation. It may be severe enough to cause death, but it occurs as a result of vasospastic or neurogenic causes. This vasospastic type of angina pectoris frequently has its inception in a severe emotional shock. Therefore, it is quite possible, in the case under consideration, that no coronary disturbance inconsistent with the age of the patient existed at any time. It is quite possible that the tendency to active coronary spasm was induced by the emotional shock of the accident. It seems likely that the presence or absence of the vasospastic element determines the presence or absence of angina in different patients with equal amounts of coronary damage. It is possible that frequent attacks of spastic angina may damage the coronaries and cause thrombosis but that the thrombosis may occur as a direct result of the spasm and without additional damage.

On the other hand, the opponents of the vasospastic theory would say that coronary disease must surely have existed in this patient before the accident, but that it was not sufficiently extensive or not properly situated to produce pain. It is quite possible that the heart may have been injured in such an accident. It is probable that hearts are injured much more commonly than has heretofore been assumed. The "steering wheel heart" injury has been discussed rather commonly. Or the trauma and excitement of the accident may have caused the rupture of a small atheromatous abscess into a coronary vessel and produced enough immediate change to account for the sudden appearance of the symptoms. It is not only the extent of the coronary change but also its location that determines the presence or absence of anginal pain, and the same criteria govern the presence or absence of physical and electrocardiographic signs.

The progress of this case was that of an ordinary disease which terminated in coronary occlusion. The occlusion might easily have been hastened by the enforced bed rest with its attendant fall in blood pressure. The hysteria and nervous instability were the result of the almost continuous anginal distress and its associated apprehension.

To the neutral observer, it would appear that the adherents of the vasospastic theory have somewhat the better of the argument here, but, without a necropsy, it would be difficult to convince the opponents.

### PENETRATION OF TISSUE BY FUEL OIL FROM DIESEL ENGINE

*To the Editor:*—I would appreciate any information you can give me on the subject of piercing wounds by fuel oil under high pressure and the complications and treatment arising from these conditions because of the fuel oil penetrating the tissue and absorption from the blood stream. I feel that this type of accident is new in this country, as the work on the Diesel engine pump is but a recent industry in the United States.

E. M. FEIMAN, M.D., Canton, Ohio.

**ANSWER.**—A somewhat analogous situation has appeared in the refrigeration industry. There leaks of liquid sulfur dioxide in oil, under pressure, have caused severe eye injuries, not so much from penetration of the eye as from instantaneous freezing of areas of the orbit. In the case of the Diesel engines, the number of substances that may be used under pressure for fuel is high, ranging all the way from naphthalene compounds to peanut oil. Other fuel possibilities are the oils from the soya bean, coconut, shale, coal tar and liquid petrolatum. In addition to the basic fuel, various enhancing agents may be added, many of which are decidedly toxic under proper circumstances. These agents include divers nitrites and nitro compounds. Obviously, three types of injuries may arise in connection with the variety of accident under discussion: direct trauma, chemical action at the site of the original trauma, such as paraffinomas from paraffin oils, carcinogenic action from shale oil and other carcinogenic agents, and oil emboli. Although these potential chemical hazards are mentioned, it is emphasized that at present

scientific basis. He must evaluate medical discoveries and discard or apply them in a truly scientific manner." In the ensuing chapters the author discusses contraception, abortion, birth control, sterilization laws, sex education, euthanasia, the divorce problem and mental unfortunates. He covers ground here that has been hashed over in newspapers and periodicals and does not seem to throw much additional light on these important subjects.

*Proceedings of the National Conference of Social Work [Formerly National Conference of Charities and Corrections] at the Sixty-Third Annual Session Held in Atlantic City, New Jersey, May 18-23, 1936.* Published for the National Conference of Social Work. Cloth. Price, \$3. Pp. 655. Chicago: University of Chicago Press, 1936.

Papers included in these proceedings furnish a cross section of the current opinion of social service workers. The attitude of approach is suggested in the presidential address of Mgr. Robert F. Keegan, who says:

Today deeply disturbed voices are protesting that freedom without security is a hollow mockery, that the door of individual opportunity is rapidly closing, and that economic slavery is descending upon large masses of our people. We may not subscribe to this thinking but we cannot ignore it.

It may be significant that there are more papers on the importance of individual, personal contacts through case work than have appeared in the reports of similar conferences for several years. At the same time there is a constantly reiterated demand for more extensive governmental action in the direction of social security, the extension of public relief, and work for the unemployed. There is repeated recognition of the fundamental influence of low wages on social problems and the need for increasing incomes in the low brackets, backed up by repeated references to the income statistics of the Brookings Institute. There are also several attempts to integrate these measures in proposals for general social planning, especially in its relation to the problem of unemployment.

*Topography of the Layer of Rods and Cones in the Human Retina.* By G. Osterberg. Paper. Pp. 102, with 8 illustrations. Copenhagen: NYT Nordisk Forlag: Arnold Busck, 1935.

This book is another of the excellent series of monographs on ophthalmologic subjects that have appeared from the eye clinics of the Scandinavian countries. It begins with a historical review of the literature on the results of the earlier investigations on the form and number of rods and cones. An introduction discusses the errors of the various methods of fixation, embedding, sectioning and counting. Finally the estimation of the number of rods and cones per square millimeter at measured distances from the macula is recorded. The center of the fovea contains 147,300 cones per square millimeter. The so-called rod line 130 microns from the center of the fovea shows 74,800 rods per square millimeter. A minimum of 3,300 cones per square millimeter is found 10 mm. temporally from the center. The rods begin 130 microns from the foveola. About 5.5 mm. from the center there is an annular zone containing a maximal concentration of rods. Near the ora serrata the number of rods shrinks to between 23,000 and 50,000 per square millimeter. There are between 110,000,000 and 125,000,000 rods and between 6,300,000 million and 6,800,000 million cones in the normal human retina.

*Étapes de la neurologie dans l'antiquité Grecque (d'Homère à Gallien).* Par A. Souques, médecin honoraire de la Salpêtrière. Paper. Price, 45 francs. Pp. 247. Paris: Masson & Cie, 1936.

One would think that an author dealing with historical subjects in neurology in French would be somewhat awed by the fact that Soury's massive work on the nervous system was written in that language and covers thoroughly the problems of neurology as recognized and described by classical authors. Naturally, since Soury's work is not recent there have been some improvements in contemporary knowledge of neurology which might make it worth while to reread some of the authors to see if there is any indication that newly recognized conditions were noted or described in antiquity. The present volume has a slightly different slant than that of Soury: while both refer to classical literature and contemporary criticisms of it, the present volume deals with antiquarian studies which are more recent and there is more discussion based on the author's reaction to contemporary criticism of the classical medical writers. A few new angles are presented, the chief one of

which is the demonstration of the fact that the majority of writers from Hippocrates to Galen recognized the existence of jacksonian epilepsy. The present volume largely looks at the neuropsychiatric problems from the standpoint of organic disorders, and contributions in functional neurology are slurred over to some extent. It does make interesting reading and is a worthy supplement to Soury and is commendable in the sense that it is a thorough work which adds to our cultural knowledge of the background of neurology. Its weak points are the fact that it does overlap Soury's work to a great extent and the fact that it is not annotated and does not have an index. The style is easy even for those who are relatively unfamiliar with French.

*Spending to Save: The Complete Story of Relief.* By Harry L. Hopkins, Federal Emergency Relief Administrator. Cloth. Price, \$1.50. Pp. 197. New York: W. W. Norton & Company, Inc., 1936.

This book is far from "the complete story of relief" which the subtitle indicates. It is a dramatic story of the conditions that arose out of the depression of 1929 and the reluctance of governments to recognize the extent and duration of the ensuing poverty and the consequent need of organized relief on a national scale. It is also a spirited and able defense of such measures as the CWA, WPA, FERA, CCC, and to a lesser extent the AAA. The only reference to the medical relief given is to say (p. 102) "We paid for medicine and sometimes for the doctor." The failure to apply the principles of civil service is almost completely ignored. The program of permanent action is sketchy; perhaps the difficulty of outlining such a program makes this excusable. The social security legislation is praised and the policy laid down that in the future (p. 181) "Federal aid, I believe, should be given through the Social Security Board which with similar state and county boards, should pass this benefit as a pension without stigma to those who need it." If this is to be done "an adequate civil service made up of permanent employees is absolutely essential to the success of any pension system." This is the only mention of civil service. Such a plan will not take care of 400,000 workers who come of age each year, the casual laborer, the agricultural or the household workers, and these, it is held, can be taken care of only by work programs.

*Einrichtung und ordnungsgemässer Betrieb der chirurgischen Krankenstation.* Von Dr. Richard Goldhahn, Chefarzt des Kreiskrankenhauses in Liegnitz. Boards. Price, 4 marks. Pp. 128, with 33 illustrations. Leipzig: Georg Thieme, 1936.

This booklet serves as a supplement to the treatise by Kappis on organization and management of the operating room and is intended primarily as a guide for interns and resident physicians, to avoid repeated oral instructions and to secure uninterrupted service in surgical wards. Various chapters deal with the construction and furnishing of the wards, schedule of ward walks and dressings, admission of patients, asepsis and antisepsis, certain procedures such as venoclysis, blood transfusions and the application of casts, diets, preoperative and postoperative measures, transportation of patients, preservation of utensils, history taking and similar topics. Contrary to the experience in this country, the author complains of scarcity of private and semiprivate rooms in the hospitals. As window screens are not in general use on the continent, much space is devoted to the discussion of the problem of combating flies. The rules laid down in various sections of the booklet are arbitrary and rather primitive; nevertheless it probably will serve a useful purpose for young assistants in Germany, as the text is completely shorn of nonessentials.

*Diseases of the Nails.* By V. Pardo-Castello, M.D., Dermatologist and Syphilologist to the Children's Hospital, Havana, Cuba. With a foreword by Howard Fox, M.D., Professor of Dermatology and Syphilology, New York University. Cloth. Price, \$3.50. Pp. 177, with 94 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1936.

This is a useful monograph. It is practical, short and plainly written. There is a liberal amount of illustrations in black and white, and there is a full index. Its contents are chapters on the anatomy and pathology of the nails, disorders peculiar to the nails, nail dystrophies, manifestations in the nails of dermatoses and of systemic diseases, and congenital disorders of the nails. In addition there is a list of occupations in which diseases of the nails are common and one of unusual symptoms.

even though such improvement may be only temporary. The treatment should be repeated at intervals of four weeks for some time and should be supplemented by subtolerance doses of iodides.

#### ANOREXIA (?)

*To the Editor.*—My daughter, aged 11½ months, has anorexia, which does not respond to any treatment. The anorexia is of seven or eight months' duration. The birth weight was 7 pounds 1 ounce (3,200 Gm.). Delivery was spontaneous. The present weight is about 24 pounds (11 Kg.) or perhaps more. The child's health has always been good except for two colds of short duration and recent nonsuppurative otitis media. The hemoglobin and red blood cell count are above normal. The urine and stools are normal. The child is good natured; she seldom cries, is cheerful and playful, and is alert and apparently well. She was breast fed for one month and then put on cow's milk with a preparation of maltose and dextrin, because of lack of quantity and quality of the breast milk. Intolerance to cod liver oil prompted a change to halibut liver oil with viosterol. The child sleeps about twelve hours during the night but little during the day. She does not like milk and drinks from 16 to 18 ounces out of 32. She eats vegetables in small amounts—not sufficient—and dislikes fruits except for cherry juice. She eats pabulum twice a day heartily and one whole egg daily, preferably raw in cereal but sometimes cooked. She dislikes or will not eat such foods as liver, chicken, lamb chops, soups, prunes, bread and butter. She will not eat potatoes. She does not appear hungry at any time and does not cry for food. She does not vomit except when given prunes, peaches or cottage cheese, and then will vomit in fifteen minutes or half an hour after ingestion. She has never had candy or sweets. Tissue turgor is good. The child is not cranky. She crawls, sits and can stand with support. She can pull herself up to a standing position. She has six teeth. There are no signs of rickets or constitutional disease. She dislikes brewers' yeast even when it is disguised. Diphtheria toxoid at 6 months resulted in a negative Schick test with little reaction. Pertussis vaccine at 8 months resulted in a severe reaction both locally and generally. Smallpox vaccination at 10½ months gave a good take without constitutional reaction. Physical and laboratory examinations have always been negative. The weight is becoming stationary though growth is increasing. I would appreciate an opinion as to the cause of the anorexia and suggested treatment. This child can miss a meal or more without showing any hunger. Please omit name.

M.D., Wisconsin.

*ANSWER.*—If this query is correctly interpreted, it would appear that there is no cause for anxiety over this baby. The child seems in every way normal; indeed, the weight at 11½ months is better than the average. The fact that the child is happy would also indicate that she is well. Furthermore, the infant can stand and pull herself up, which shows that her static development is progressing normally. The fact that she has six teeth indicates that her nutrition is adequate despite her diminished appetite. One need really not worry about this baby. If she will take only 16 to 18 ounces of milk a day, it will suffice. The egg is beneficial, and the only criticism about its administration is that it should be boiled at least three minutes instead of being given raw. If the baby is put on three meals a day of foods that she relishes—of course, one should not omit saying that the selection of foods should be reasonable and adapted to a child of this period—the baby will prosper in her own way. The greatest mistake one could make in the management of such a case is to overglorify the baby's meal time. One should not force the food or distract the child by the various methods in vogue. If the baby is left to her own devices she will eat what she wants and in all probability all that she needs, because certainly a baby of this normal development will not starve.

#### EFFECTS OF AIR CONDITIONING AND HUMIDIFICATION ON TISSUES

*To the Editor.*—The following item quoted as being an expression of opinion of Dr. Thomas Hubbard in your publication on the subject of humidification has been brought to our attention and we should like to verify it: "The skin, like the respiratory mucous, is actually damaged by hot, dry air (and likewise the hair) and becomes more liable to chronic diseases." We shall appreciate this information and any other view you may be willing to express on the desirability of humidification in the home and the office.

LOWELL AIR CONDITIONING CORPORATION, Philadelphia.

*ANSWER.*—Under various industrial conditions involving high, arid temperatures, opportunity may be provided for actual damage to the skin, hair or mucous membranes. However, it is not known that the humidification of such air would increase comfort of the worker or eliminate the probability of some injury. This statement does not apply to ordinary atmospheric conditions in homes and offices. At the present time the best thought with respect to air conditioning places emphasis on dehumidification in the procurement of comfort in the presence of high temperatures, and humidification in the presence of low temperatures. Customarily, this means dehumidification

during summer months and humidification during cold weather. The present-day practice of increasing comfort through air conditioning, through the medium of marked diminution in temperatures between outside air and air in homes and buildings, is open to valid criticism. It is possible that quick changes from artificially chilled air to very hot outside air may be associated with demonstrable injury and possibly may be associated with an increased frequency of such diseases as pneumonia. Sufficient facts are not now available on which to predicate any unequivocal statements. At the present time it appears to be true that the chief benefit derivable from air conditioning, as now applied, is one of comfort. While it is the belief of many physicians that air conditioning promotes health for the majority of persons, there is still lacking precise proof of this belief. In some large buildings equipped with continuous air conditioning, medical experience has developed indicative that no diminution has appeared in the number of ordinary respiratory infections.

#### CALCULATION OF WEIGHT FROM AGE AND HEIGHT

*To the Editor.*—Given the age and height of an individual, is there any key to calculate the normal weight without a standard chart as a guide? Kindly omit name.

M.D., New York.

*ANSWER.*—So far as we know, no such formula has been evolved. The inherent difficulties seem obvious, because the relation between age, weight and height varies in different age periods and also in the same individual. The fact of the matter is that our height and weight tables do not represent actual standards but only approximate averages. With such variable data a mathematical formula would be of no value. If one attempted the solution of such a problem one would have to obtain an equation in which the weight could be expressed as a function of the height and age. Since there is no constant relation between age, height and weight, such a formula would be useless, and any result obtained would lack mathematical validity. We simply do not possess the information necessary to state the range of variations which should be regarded as normal in each case. There are many factors to be considered in height and weight for a given age, such as season, nutrition, exercise and mental activity. There are individual differences among races, as well as among children from wealthy and poor families. Therefore a mathematical expression of the relationship does not seem feasible.

#### FEELING OF FAINTNESS AFTER BOWEL MOVEMENT

*To the Editor.*—Can you suggest any cause and any treatment for the symptom of extreme weakness which comes on immediately following any bowel movement? The patient is 77 years old but has had this trouble for thirty years. It has grown worse during this time of advanced age. There is a slight stricture of the anal canal due to a hemorrhoid operation, but this is only slight and the complaint antedated the operation. There was an attack of coronary artery disease a year ago, from which the patient made an extraordinarily satisfactory recovery, but the complaint antedated this event by many years. The blood sugar curve, after a sugar tolerance test, shows no rise in the blood sugar above 110, but this complaint, while somewhat relieved by taking food, is characteristically present after a bowel movement and is so severe that the patient must go to bed for hours after the bowel movement. A barium sulfate enema showed the colon rather capacious with absence of haustral markings in the transverse and descending portions and with no evidence of an organic lesion. Please omit name.

M.D., California.

*ANSWER.*—This syndrome for a man or woman to feel faint and weak after a large diarrheic bowel movement is more or less natural. It seems probable that the same type of distress in an exaggerated form can occur occasionally in persons who have feces of normal consistency. In such cases one would expect to find that the reflexes either of the patient as a whole or of the lower part of the abdomen are exaggerated. Actually, in most instances the patient is a highly sensitive and nervous woman.

Because one can find this syndrome in patients who haven't the slightest sign of disease in the colon or rectum or lower part of the abdomen it seems best to disregard as accidental any small abnormalities which can be found in a particular patient.

Under the circumstances the most logical treatment would seem to be the giving of some sedative, such as sodium bromide, half an hour before the patient expects to move the bowel. Sometimes one of these patients can be helped most by being taught to live on a low residue diet which will enable her to go for three or four days without a bowel movement. In this way she will have only two ordeals a week instead of one every day.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Death Due to Paralytic Ileus Following Herniotomy.**—The employee in this case was injured, September 11, when his left leg broke through the wood cover of a manhole. He quit work immediately and had difficulty in getting to his house. He complained of nausea and of pain in the lower left side of his abdomen. That evening there was a pronounced swelling and tenderness in the left inguinal region. Two days later his condition was diagnosed as traumatic hernia. Rest until the swelling and tenderness disappeared was advised. A herniotomy was performed, October 29. Twelve hours later the employee's abdomen became distended and within a day or two his condition was described as toxic. He died November 3, the immediate cause of death being "paralytic ileus; i. e., paralysis of the small intestine." The employee's widow was awarded compensation under the workmen's compensation act of Wisconsin and the employer and insurer appealed to the Supreme Court of Wisconsin after the circuit court had affirmed that award.

The appellants contended that, since the operating physician found conditions at the time of the operation which clearly indicated that the hernia was not of recent origin, the commission was not justified in finding that the employee sustained a hernia as a result of the accident. But, said the Supreme Court, it was immaterial whether the hernia had existed prior to the accident. If it did exist, it was certainly greatly aggravated by the accident and resulted in a compensable injury. While there was no suggestion of carelessness or lack of skill on the part of the operating physician, it was clear, in the opinion of the court, that the commission was warranted in finding that an accident occurred, that it resulted in an injury which reasonably necessitated an operation, and that as a result of the operation infection entered the abdomen which ultimately caused death. Whether the infection entered in spite of the exercise of the highest skill or as a result of lack of skill or carelessness was immaterial. If an employer must compensate an employee for injuries caused by the malpractice of a physician who treats the employee for an industrial injury, and such is the law, an employer must likewise compensate an employee, or his dependents in case of his death, for injuries resulting from an operation skillfully performed. The award of compensation was affirmed.—*Stiger v. Industrial Commission* (Wis.), 265 N. W. 678.

**Malpractice: Liability of Physician for Abandonment of Patient.**—The defendant, a physician, was engaged to attend the plaintiff during the latter part of her pregnancy. Prior to her confinement she had "a hemorrhage," the date of which is not given in the record. About three weeks thereafter, in the early afternoon, she had another "hemorrhage" and the defendant was called and attended her at her home. The patient continued to lose blood and to suffer pain and at midnight the defendant again responded to a call. Shortly after 8 o'clock the following morning the defendant, at the behest of the plaintiff's husband, called on the patient and found her still bleeding and in severe pain. Arrangements were immediately made to transfer the patient, in an ambulance, to a hospital. The defendant did not accompany the patient. On her arrival at the hospital she was cared for by nurses, who "gave her pills, injections and so on." Later two physicians, apparently at the instance of the hospital authorities, attended the plaintiff. During this time the plaintiff's husband and others made repeated attempts by telephone to get in touch with the defendant but he could not be located. He did not appear at the hospital until 3 o'clock that afternoon, either just before or after the plaintiff gave birth to a child that did not survive. In a suit subsequently instituted by the plaintiff against the defendant, she alleged that he was guilty of a breach of his professional duty in that he neglected to accompany her to the hospital, failed to be present during her labor and childbirth, and failed to render such treatment as would

have stopped her bleeding and insured the delivery of a living child. She sought recovery of damages for pain which she had suffered and would continue to suffer, and for great mental and physical anguish caused by her having given birth to a dead child. The trial court directed a verdict for the physician and, from the judgment entered on that verdict, the plaintiff appealed to the Supreme Court of Michigan.

The Supreme Court did not pass on the plaintiff's contention that she was legally entitled to the personal care and attendance of the defendant. It did say that the evidence showed that, through the defendant's arrangements for her removal to the hospital, she had received professional care and attention and that there was no competent testimony that the defendant's failure to attend her in person resulted in her suffering any greater pain than she otherwise would have suffered, or that the unfortunate outcome of her confinement was caused by his absence. Furthermore, in the opinion of the court, the record failed to show that the defendant by proper care could have and should have caused cessation of her hemorrhages. In short, the plaintiff failed to show, the court concluded, that she would have suffered less or that she would have escaped any of the elements of damages for which she sought recovery had the defendant attended her in person during the interval he was absent instead of causing her to be placed under the care of other skilled persons. The judgment for the defendant was affirmed.—*Jackowicz v. Knobloch* (Mich.), 265 N. W. 799.

**Fraudulent Application for Annual Registration Receipt in Relation to Crime of Forgery.**—The medical practice act of Texas requires all persons practicing medicine in the state to register annually with the board of medical examiners. On completion of this registration, the board sends to the applicant an annual registration receipt which evidences his right to practice medicine for the ensuing year. Christian, an unlicensed person, executed an application for annual registration, signing to the application the name of a physician who formerly was a Texas licentiate. He was tried and convicted of forgery and appealed to the court of criminal appeals of Texas.

Christian contended that his act did not constitute the crime of forgery, which is defined by Article 979, Texas Penal Code, as follows:

He is guilty of forgery who without lawful authority, and with intent to injure or defraud, shall make a false instrument in writing purporting to be the act of another, in such manner that the false instrument so made would (if the same were true) have created, increased, diminished, discharged or defeated any pecuniary obligation, or would have transferred, or in any manner have affected any property whatever.

That the application for reregistration did not create or in any manner affect a pecuniary obligation was apparent, said the court. Did it affect property? A certificate to practice medicine, and the annual registration receipt, confer a valuable right on the person to whom they are properly issued. The right to practice is a privilege but is not property in the sense in which that word is generally understood. Evidence of the right to exercise the privilege, however, should not be confused with the privilege itself. In the opinion of the court, the annual registration receipt itself constituted property within the meaning of the statute relating to forgery and Christian's conviction was consequently upheld.—*Christian v. State* (Texas), 92 S. W. (2d) 1032.

### COMING MEETINGS

American Orthopsychiatric Association, New York, Feb. 18-20. Dr. George S. Stevenson, 50 West 55th St., New York, Secretary.  
Annual Congress on Medical Education, Medical Literature and Hospitals, Chicago, Feb. 18-19. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.  
Pacific Coast Surgical Association, Seattle, Wash., Feb. 19-21. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.  
Southeastern Surgical Congress, Louisville, Ky., March 1-5. Dr. Benjamin T. Beasley, 47½ Peachtree St. N.E., Atlanta, Ga., Secretary.  
Western Section, American Laryngological, Rhinological and Otolaryngological Society, San Diego, Calif., Jan. 21-22. Dr. Daniel P. Hildner, 100 Fourth Ave., San Diego, Calif., Chairman.

bromide: it does not accumulate in nerve tissue. Its mode of action may be visualized by assuming that it goes into "partnership" with chloride and acts chiefly by rendering the tissue fluid less suitable for optimal function of the tissues: the central nervous system, the most reactive of the body, chiefly showing the result in the way of a depression. Maximum effects result when there is bromide saturation of the system; i. e., when as much bromide is eliminated as is ingested. Fatal poisoning by means of bromide is rare and not likely to occur in a normal individual. The 5 grain dose of chloral is a more potent sedative than a 15 grain dose of bromide.

#### STAMMERING, BLINKING, AND LEFT HANDEDNESS

To the Editor:—I have been doing orthoptic training for my husband, who is an ophthalmologist, and for other ophthalmologists in Philadelphia for several years. This year I have also done a great deal of examining among nonreaders in public and private schools for possible fusion difficulty as a basis of poor reading or failure to learn to read. I have therefore seen a number of cases of fusion difficulty that have not reached the stage of actual crossed eyes, as well as treating the ones whose eyes have already crossed. It is common to see left handed children with fusion difficulty, whether they have also developed stammering or not. I have several cases that combine left handedness, stammering and crossed eyes, but the stammering is not necessary to the picture. I was therefore much interested in the note in *THE JOURNAL*, May 9, 1936, regarding "Stammering, Blinking and Left Handedness," in that you do not so much as suggest an eye examination for a 6 year child who has developed a marked blinking. The child is, one presumes, learning to read in the year that he has developed the blinking, and a fusion difficulty would be accentuated and can well cause the marked blinking. Could this suggestion be forwarded to the original questioner, as there are many doctors in New York interested in the fusion problem, and he could have the benefit of their advice?

DOROTHY E. BERNER, Philadelphia.

ANSWER.—The coincidence of stammering, blinking and left handedness is extremely interesting and not well known. Calling attention to the rôle of blinking in this syndrome is timely. Blinking as a result of defective fusion should certainly be investigated in every case.

#### SIGNIFICANCE OF DARK CIRCLES UNDER EYES OF CHILDREN

To the Editor:—I should appreciate being told whether you know of articles concerned with the occurrence of dark circles under the eyes in children. It is a sign much used by mothers in the evaluation of the child's well being but one about which I have been able to get no definite information of a scientific nature. Please omit name in reply.

STUDENT, New York.

ANSWER.—Edema and pigmentation may occur in anemia of every grade or may be due to sunburn, recent localized hemorrhages, urticaria pigmentosa, insect bites, Addison's disease, or long continued medication with arsenic, lead, santolin, or silver compounds. Edema of the eyelids also occurs in heart or kidney disorders or in thromboses of the cerebral sinuses. Pigmentation of the eyelids may also occur in exophthalmic goiter, which is rare, however, in young life. It should be recalled, too, that the infantile eyelids contain a larger percentage of fat and loose areolar tissue than is supplied to the adult. They are consequently prone to excessive swelling in the presence of inflammatory changes that occur after infection or injuries. Fatigue, loss of sleep, slight injury, and minor causes of any kind may produce swelling and discoloration in the region of the lower eyelid without special pathognomonic significance.

#### CHRONIC CONJUNCTIVITIS

To the Editor:—A bank teller, aged 24, for the past one and one-half years has been suffering with a severe painful burning of the lids of both eyes. This burning is peculiar in that it is always worse in the morning for several hours after arising and is considerably worse following a long night's sleep after retiring early. He has been treated by several good ophthalmologists without results. Examination shows a simple moderate injection of the palpebral conjunctiva of each eye. Refraction shows —25 in each eye. Painting the conjunctiva with a 2 per cent silver nitrate solution gives some relief for three to six days, although it is most painful when this is done for as long as from four to six hours. Zinc, mild protein silver and wearing glasses are of no help. Please omit name.

M.D., Florida.

ANSWER.—The increase in severity of symptoms after arising suggests a form of conjunctival inflammation that is due to incomplete closure of the palpebral aperture during sleep. The patient might try filling the conjunctival sac with ordinary petrolatum on retiring, thus preventing exposure during the night. It is also possible that a muscular imbalance may be concerned in the maintenance of the conjunctivitis.

#### REMOVAL OF TONSILS IN CHILD OF STATUS LYMPHATICUS TYPE

To the Editor:—In the case of children known to be of the status lymphaticus type, what would be the most desirable narcosis in case of performing tonsillectomy?

V. W. JENSEN, M.D., Shelby, Mich.

ANSWER.—Every operative procedure in the case of status lymphaticus is fraught with the greatest possible danger. It is difficult to conceive that any anesthetic would lessen this danger even if it should be a light ether anesthesia or one with ethylene. Removal of tonsils is hardly ever so imperative that a risk of operative death should be undertaken. If the tonsils are so large that they cause mechanical disturbance, roentgen irradiation has a selective effect on the lymphoid elements of the tonsils and by reducing them reduces the size of the tonsils. If the child is old enough to submit to it, partial destruction of the tonsils may be attempted with electrocoagulation. Although this is not a universally accepted procedure for complete removal of the tonsils, in the hands of some it has been successful but usually requires quite a number of sittings.

#### MENTHOLATED CIGARETS—DISINTEGRATION OF TABLETS

To the Editor:—1. Is there any evidence that the smoking of mentholated cigarettes is harmful because of the menthol? 2. If a compressed tablet containing acetylsalicylic acid 3 grains, phenacetin 2 grains, caffeine alkaloid one-fourth grain and tincture of gelsemium 2 minims disintegrates rapidly on being placed in a glass of plain water, does this necessarily mean that this tablet will act sooner than one of the same formula that does not disintegrate when under similar conditions? Please omit name.

M.D., Michigan.

ANSWER.—1. There is no evidence that smoking mentholated cigarettes is harmful.

2. Rapid disintegration of a compressed tablet may not be taken as a guaranty that the tablet will act promptly; lack of disintegration under similar conditions leaves the question open whether disintegration does or does not occur in the intestinal tract.

#### ORTON THEORY OF CEREBRAL DOMINANCE AND STAMMERING

To the Editor:—In answer to a question on stammering in *Queries and Minor Notes* in *THE JOURNAL*, May 9, 1936, page 1681, you reply that Orton has developed an intricate theory of cerebral dominance which is not particularly intriguing but that the empirical observations have been confirmed. Can you tell me on what material or reports you base these observations?

I. J. WOLF, M.D., Paterson, N. J.

ANSWER.—Further details are given by S. T. Orton in the *Archives of Neurology and Psychiatry* 14:581 (Nov.) 1925 and in the *Transactions of the Association for Research in Nervous and Mental Diseases* for 1935. His theory and case material are adequately presented in his published work.

#### HAZARDS IN ETCHING INDUSTRY

To the Editor:—I noted with interest a brief discussion entitled "Hazards to Etching Industry" in *Queries and Minor Notes* in *THE JOURNAL*, Nov. 21, 1936. The inquiry contains the question "Do you see any possible reaction in the etching process that would account for the ammonia fumes?" In the answer to the inquiry it is specifically stated that it is unlikely that any ammonia would be produced and it is suggested that a combination of various pungent odors might be mistaken for ammonia.

While I agree with the author of the answer that ammonia is probably not the cause of the ulcerations that were responsible for the inquiry, he is mistaken in saying that ammonia is not likely to be produced in plating processes. The cyanide bath is often an important source of ammonia; in fact, the chief loss of cyanide may be due to its hydrolysis to ammonia. The reaction may be written as follows:

This reaction also forms the basis for one of the methods for nitrogen fixation, in which the nitrogen of the air reacts with sodium carbonate and coke to form crude sodium cyanide, which is then treated with steam, hydrolysis to ammonia and either sodium carbonate or sodium formate resulting.

Tests made by this laboratory in electroplating rooms have failed to disclose appreciable concentrations of cyanide in the atmosphere, the highest value being less than 2 parts per million. It is possible, however, that if there is much spattering of solutions or if the plating is carried out with a heavy overvoltage the air might be contaminated with larger quantities of cyanogen compounds.

**Enucleation of Superior Thyroid Pole.**—Eades considers his method of attacking the superior pole as an enucleation maneuver. The usual thyroidectomy technic is followed to the point at which the glandular capsule has been reflected laterally to where it merges with the coverings of the lateral neurovascular bundle, the carotid sheath. The suspensory ligament of the lobe under attack is then incised and ligated and the lobe is rotated slightly away from the larynx. Two pilot clamps are then placed on the middle thyroid vessels (vein) and the lower polar vessels. After the glandular mass of the lobe being attacked is elevated from its bed by Lahey grasps, the middle thyroid vein is divided and ligated, and the enucleation of the superior pole is begun by placing a Lahey tenaculum on the glandular substance high up near the superior pole and gentle traction is made. The portion of the glandular capsule that is reflected on the vessels is put on the stretch. The included vessels suspend the capsular tissues after the manner of a blanket hanging over a clothes line. A clamp is then placed high up on this raised edge (ridge pole of tent) and another is placed a slight distance below it and the included vessel is incised. By making slight traction on the lower clamp a triangular hiatus in the fibrous tissue beneath the upper clamp is observed. The handle of the scalpel can then be placed between the so-called tent flaps and the upper pole is enucleated upward to the point at which the next vessel branch is put on the stretch. The procedure is repeated after traction is placed on the tenacula and the upper pole is drawn down farther. Stretching or angulating of the upper end of the recurrent laryngeal nerve should be avoided. After the upper pole is delivered, there will be from three to five small terminal branches of the superior thyroid artery held in clamps. These are turned to the side and covered with gauze. The lobectomy is then completed by dividing the isthmus and removing the desired amount of the gland substance. The vessels of the inferior pole are ligated, as are those within the thyroid remnant. The clamps on the terminal branches of the superior thyroid artery and vein are ligated last, when the exposure is the best.

**Peritoneal Immunization.**—Johnson states that the rationale of peritoneal immunization is based on the physiology of the peritoneal defense mechanism, which is dependent on the

exciting presence of bacteria and their toxins, foreign bodies, irritating chemicals or harmless substances that excite a similar peritoneal response. Antigenic substances known to produce a high leukocyte count, lytic agents, dextrose, amniotic fluid and bacterial vaccines are the substances that have been most extensively employed. Digestive agents or substances that induce the formation of a tremendous peritoneal transudate interfere with fixation and localization and are dangerous in the presence of infection. Highly irritating and destructive substances may induce the production of a large exudate histiocyte count. Such a cellular response to destructive irritants renders the histiocyte an unreliable means of measuring the protective effect of a given agent. The late cellular response to the use of amniotic fluid concentrate compares favorably with the response to the use of Bagen's vaccine. The mortality and morbidity of postoperative peritonitis have been influenced favorably by peritoneal immunization. There is at present no reliable measure of the effectiveness of a given activator other than the clinical results attendant on its use. Amniotic fluid concentrate does everything that any known agent can do in the way of early, local protection against postoperative peritonitis without the undesirable features connected with the use of other substances.

## Am. J. Syphilis, Gonorrhea and Ven. Dis., St. Louis

20: 583-706 (Nov.) 1936

**Probable Mechanism of Cure in Gonorrhea.**—Herrold states that it has been established that alteration of gonococci in vitro is dependent on unfavorable environment for reproduction of normal types. Since they occur in predominance during favorable clinical response, it would seem logical to assume that biochemical factors in vivo are likewise responsible and might explain the mechanism of cure. Tentatively, the hypothesis seems justified that in vivo coccus forms are associated with the earliest definite changes and, consequently, perhaps the more easily revertible to typical gonococci with clinical exacerbation of symptoms. It is possible that the diphtheroidal type may be the more stabilized and thus produce mild or no symptoms, with final eradication or existence for variable periods of time as saprophytes. It is not unusual for typical gonococci to remain for periods of several months after clinical symptoms have subsided, contributing to grave difficulty in the epidemiologic reduction of gonorrhea.

have been profitably omitted and others which could have been amplified. But in the main this textbook is a well organized, terse and provocative presentation of essential, current information in biochemistry for the medical student. It would seem to be of greatest usefulness for the medical student in his later years of training.

**Clinical Investigations Into the Action of Protamine Insullinate.** By Niels B. Krarup. Paper. Pp. 116, with 75 illustrations. Copenhagen: G. E. C. Gad, Publisher, 1935.

Krarup describes his studies on protamine insulin carried out during his appointment under Dr. H. C. Hagedorn at the Steno Memorial Hospital in Copenhagen from 1933 to 1935. Each one of the pages and of the charts bound with the text shows careful composition and the desire of the author to improve the treatment of diabetes. In *THE JOURNAL*, Jan. 18, 1936, an article by Hagedorn, Jensen, Krarup and Wodstrup gave the details of preparation of protamine insulin with a few illustrative charts showing its effect. In his monograph Krarup takes up in detail the clinical side of the picture and reports the results obtained in the first forty-one cases treated with various preparations. He precedes the description of the actual experiments with chapters on the clinical testing of medicaments with special reference to the condition obtaining in diabetes mellitus. He discusses the basis for the use of protamine insulin, describing efforts previously made in various lands by many people to prolong the action of insulin. Then follow the methods employed for the clinical tests; these disclose the high standards maintained in all the investigations with protamine insulin. There were 11,000 blood sugar determinations in addition to a great number of tests of sugar and ammonia in the urine. In a series of cases a comparison of the action of protamine insulin with regular insulin is made when the former was administered in the evening, both morning and evening, or once a day. In the preface Krarup states that an even better effect was obtained with a combination of a protamine from *Salmo irideus*, the rainbow trout, than with the salmine and scrombrine insulin that were used in the experiments reported. Krarup reaches the definite conclusions that protamine insulin acts approximately twice as long as regular insulin, that its utilization is greater and its effect more uniform than that of ordinary insulin, and that it can be used advantageously to lessen the fluctuations in the blood sugar and the consequent glycosuria and tendency to acidosis during certain hours of the day.

**Tissue Immunity.** By Reuben L. Kahn, M.S., D.Sc., University of Michigan, Ann Arbor. Cloth. Price, \$7.50. Pp. 707, with illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1936.

Many physicians specifically interested in immunity are familiar with the current contributions of the author in the medical literature. This group will welcome the opportunity to read a unified presentation of the subject in monographic form. Other physicians not acquainted with work of the author will find a unique presentation of the subject of immunity. In its pages he may find the explanation of many clinical phenomena following the giving of vaccines, serums, extracts and drugs not adequately explained by conventional views on humoral and cellular immunity. The author does not seek to revise our conception of immunity but rather to enlarge our understanding of the laws governing reaction of the body cells to protein and microbial antigens. Immunity is clearly presented as a physiologic function of all cells, and the relation between immunity under natural conditions and injections is precisely indicated. The material is well organized and is presented in a convincing and provocative manner. The text is replete with protocol data and charts which enable the reader to follow the author's basis for reasoning. Abstract thinking is well fortified with experimental fact. While the literary style is a bit cumbersome in places, it is the natural result of the informality of presentation. The author is actually discussing moot points and the reader becomes a reacting agent rather than a passive recipient of information. Explanations of many clinical experiences such as the increased effectiveness of vaccine injections given at longer intervals, why smaller doses are more effective than larger ones, why vaccines administered subcutaneously are not effective for furunculosis, and a number of interesting and valuable points are vitalized by experimental data and ingenious interpretation. The book is

unquestionably a work of great importance on the subject of immunity. It exhaustively covers a broad field of interest and the clinician can glean as much from its pages as can the bacteriologist and pathologist. It is far too comprehensive to be adequately covered by a short review. Every physician should be familiar with the book and he can purchase it with the assurance that it will be a constant source of stimulation and rational thought on the subject of immunity in its broadest sense.

**Physician, Pastor and Patient: Problems in Pastoral Medicine.** By George W. Jacoby, M.D. Cloth. Price, \$3.50. Pp. 390, with 20 illustrations. New York & London: Paul B. Hoeber, Inc., 1936.

This is the third book which the author has written to present to the public the relation that medicine bears to other professions and to suggest their mutual cooperation. He has an extremely broad conception of the influence of preventive medicine on daily living and cultural development. The antagonism between medicine and religion, which has been emphasized for centuries, now in some places has given way to actual cooperation between the two in the interests of better physical, mental and moral health. Dr. Jacoby has a delightfully clear, conversational style in writing about numerous problems that impressed him during a long career as a neurologist and psychiatrist. He shows a broad cultural background and a sympathetic understanding even of some problems that are only indirectly related to the practice of medicine. In the front chapters he shows that medicine was born in the intricate culture of Old Egypt, whence the medical torch was carried to Mesopotamia, to India, to China and back to Greece, where in the fifth century before Christ Hippocrates, the great physician of all time, first attempted to establish a rational medical science. Greek medicine broke up into controversial schools after Hippocrates passed on and not for 600 years did another great physician appear, this time in Rome, where the center of Greek medical knowledge had shifted and brought forth Galen, the founder of experimental physiology. Galen fell short of the greatness of Hippocrates and yet his dogmatism was accepted as final authority for nearly fourteen hundred years. The church sponsored the teachings of Galen for centuries, and to deviate from them was to violate the sanctity of religious authority. After Galen, medical investigation stopped. Civilization entered the dark ages, and western learning was nurtured only in the bosom of the church with such nutriment as faith healing, belief in supernatural intervention and the miraculous power of saints and of holy relics. During this long dark period the one great contribution of the church to medicine was the founding of hospitals, asylums and universities. Then Arabic medicine broke through the darkness and carried the traditions of Galen into western Europe with the return of the crusaders from Palestine. Religion laid a heavy hand of restraint on medical advancement even later. When Simpson of the University of Glasgow first successfully employed chloroform in a difficult labor in 1847 the Scottish clergy "bemoaned the intervention of man in the natural obligations laid upon women by the hand of God." Chapters 7 and 8 briefly summarize the rise of the great religions of the world and their influence on medicine and public health. Here is information which one might search for through many volumes and never find, or which might escape an intelligent public entirely. Here one learns of Lao-tze, Buddha, Confucius, Daruma, Manla, Nichiren, Abraham and Moses, and also of the extent and significance of the present-day Zionist movement to Palestine. Chapter 11, entitled "The Inexplicables in Medical Practice," seems to be a misguided effort; perhaps it should have been omitted. In these few pages Dr. Jacoby does little more than mention "animal magnetism," which, he says, possessed by especially endowed persons, enables them to influence both human beings and animals by certain physical manifestations, so that a beneficial therapeutic effect will be produced. Other mysterious forces mentioned are the influence of certain colors, certain activities of light, certain tonalities of sound. He briefly discusses the question Does the moon influence health, sun spots, health and disease, and astrology and disease? He closes chapter 11, which seems foreign to the book, with the statement "While there is much which remains undiscovered and unexplained in the practical application of medicine, it is the duty of the individual physician to conduct his practice on a

ized hemorrhagic papulonecrotic eruptions are emphasized by a comparison of such an eruption occurring as a manifestation of acute aleukemic reticulo-endotheliosis with furunculosis associated with myelogenous leukemia, with staphylococci septiemia, and with a similar eruption that represented generalized herpes zoster in a patient with chronic lymphatic leukemia. A type of chronic cutaneous ulceration observed in two cases of chronic reticulo-endotheliosis may be one of the characteristic lesions of this disease. The essential feature of monocytic leukemia cutis is the infiltration with mature and immature monocytes. Such cells may be recognized by their large size and notched nuclei occurring together with other distinctive features. Acute or chronic reticulo-endotheliosis is characterized by the loose structure of the lesion; there are large reticular cells having vesicular nuclei, and within the reticular framework are large free mononuclear cells. A polymorphic infiltrate may be present. The resemblance between the pathologic changes in the specific cutaneous lesions of monocytic leukemia and of reticulo-endotheliosis is regarded as further support for the view that reticulo-endotheliosis is an aleukemic manifestation of monocytic leukemia.

**Lichen Ruber Moniliformis (Morbus Moniliformis Lichenoides).**—Wise and Rein find that of the cases recorded as instances of lichen ruber moniliformis there are only two in which microscopic examination definitely excludes lichen planus; namely, Kaposi's and their case. The similarity of clinical manifestations in these two cases and the obvious dissimilarity of the picture to that in cases in which microscopic examination revealed lichen planus seem to support the contention of the critics who regard the original "lichen ruber moniliformis" not only as a dermatosis unrelated to lichen planus but possibly as one which might prove to be a disease by itself. The histologic changes in their case would at least lead them to accept this view. There is a close parallelism between Kaposi's and the authors' case in the distribution of the lesions, their morphologic features, their multiformity, their variations in color, size and arrangement, the absence of marks of scratching, the chronicity, the similarity of some elements to papules of lichen planus, and the lack of discoverable etiologic and pathogenic features. The dermatosis in Kaposi's case differs from theirs in that the longitudinal banded keloid-like formations on the neck and extremities were far more pronounced and much more prominent in his case; in his case there were central depressions in some of the papular elements, lesions of the labial and buccal mucosa, a retiform design of papular chains on the thighs, longitudinal bands on the lower portion of the abdomen and a scattering of pigmented puncta in the midst of the other lesions. The buccal manifestations possessed none of the diagnostic features of lichen planus. In neither case was the glans penis involved. The dermatosis in Kaposi's case most likely was a manifestation of a much further advanced phase of development and evolution than that which obtained in their patient. A different name seems desirable. Taking into consideration the clinical similarity of the dermatosis exhibited by their patient to that described by Kaposi, its nonrelation to lichen planus, and the lack of etiologic and pathogenic clues to its identity, the authors suggest the neutral name morbus moniliformis lichenoides.

**Treatment of Severe Epistaxis.**—In cases of severe epistaxis in which the source of bleeding is not accessible and which cannot be controlled by the ordinary means (such as

the application of methylamino-aceto-orthodioxymethylene, galvanocautery or electrocoagulation), Hirsch finds ligation of the internal maxillary artery in the sphenomaxillary fossa the method of choice. The technic is rather simple, especially when one makes a large opening into the facial wall of the antrum at the beginning of the operation. It is not so necessary to enlarge the opening toward the lateral side, as it is imperative to remove the bone as far as possible toward the edge of the piriform opening. It is not necessary to take away the entire edge of the piriform fossa but, in order to have easy access to the anterior wall of the inferior medial border of the maxillary cavity, the incision in the oral mucosa should be made beyond the midline, so that the frenulum labii superioris is divided.

 Diffusely Infiltrative Carcinoma: Hitherto Undescribed Correlation of Several Varieties of Tumor Metastasis. S. Jarcho, New York.—p. 674.

**Significance of Hepatic Edema.**—Keschner and Klemperer studied sections of liver obtained in 505 consecutive necropsies for the presence of intralobular hepatic edema and found intraparenchymal edema in seventy-nine cases. Two types of intralobular hepatic edema occur: that due to the same physical factors which govern the development of edema in circulatory failure (mechanical edema) and that due to a primary increased permeability of the vascular wall caused by various factors not yet fully recognized (primary edema). Mechanical hepatic edema occurred in almost half of the seventy-nine cases; no difference in frequency of this condition was noted in the cases of circulatory failure due to rheumatic and those due to vascular myocardial lesions. The control series of cases, those of normal persons killed by violence, failed to reveal a single incidence of intralobular hepatic edema. The age incidence in the cases of hepatic edema was from 19 months to 75 years, with no especially prominent incidence in any particular age group. Hepatic edema was just about as frequent in cases of pulmonary embolism as in those of cardiac failure. All the persons with glomerulonephritis in whose liver edema was observed showed marked anasarca and ascites. Persons with chronic lipid nephrosis with generalized edema did not present hepatic edema. Hepatic edema was observed in 75 per cent of the cases of malignant nephrosclerosis. Except in three instances there was no clinical or anatomic evidence of even terminal cardiac failure. The proportion of cases in which hepatic edema was present was 39 per cent, far below that of cases of malignant nephrosclerosis with hepatic edema. The presence in uremia of an alteration in the chemical constitution of the blood suggested an investigation of cases of diabetic coma with the associated chemical changes of the blood. Five of eleven cases presented hepatic edema. The study of infectious diseases gave unexpectedly low figures, contrary to the statement of Roessle, Eppinger and Gerlach. Only influenza showed a strikingly high percentage (64). The negative observations in peritonitis indicate that the direct absorption of toxic products into the portal system does not necessarily cause hepatic edema. There was but one instance of hepatic edema in twenty cases of gastro-intestinal intoxication. The high incidence of hepatic edema in cases of exophthalmic goiter (43 per cent) conforms with the observations of Roessle. There was no instance of hepatic edema in eight cases of Addison's disease. Of sixteen instances of Laënnec's cirrhosis, intralobular hepatic edema was found only three times. In two of these cases the edema was associated with myocardial insufficiency, and in the third death was due to influenza. Hepatic edema was encountered in five of six patients dying in so-called status asthmaticus. In eight cases of death during operation regarded as due to the anesthesia

due to poisons. The author's purpose was to supply in English the widely scattered facts contained in the literature, together with his own observations, in a condensed yet comprehensive manner. The task has been accomplished well. It is an excellent little book to have at hand for reference.

**Die Philosophie der Selbstverständlichkeit (Fysiosofie): Ein Elementar-Versuch.** Von Franz Kalbel. Boards. Pp. 155. Welmar: The Author, 1936.

The title in English means "The Philosophy of the Self Evident" and the author calls it an elementary attempt which, unfortunately, cannot be denied. The author intends to give a world outlook, "weltanschauung," for the "man of the spirit," whom he differentiates from the "man of the masses." From then on the author states that the spiritual man is different in the structure of his brain and in his chemical and electrical properties. The spiritual man builds up his "weltanschauung" by means of logical knowledge, while the man of the masses needs ready made ideas. This is as far as one can understand the author's philosophy. The book is written in an extremely incoherent manner with a peculiar spelling of his own and without much regard for syntactical form. In a rather crude manner the author offers a philosophy of neomaterialism which assumes that the solution of all psychologic problems lies in their reduction to simple electrical changes, which can be measured by the laws of physics and mathematics. He presents an outline of a mind-soul physics that is quite fantastic. It is interesting that the book is published by the author himself, as it is obvious that no publisher in Germany would undertake the publication of the book.

**Favourite Prescriptions.** Edited by Sir Humphry Rolleston, Bt., G.C.V.O., K.C.B., M.D., and Alan A. Moncreff, M.D., F.R.C.P. Published on behalf of The Practitioner. Cloth. Price, 10s. 6d. Pp. 227. London: Eyre & Spottiswoode, Ltd., 1936.

This book, which is the collection of a series of eighteen articles originally published in the *Practitioner*, is of considerable interest if from no other than the historical standpoint. It is hoped that it does not, as claimed, "shed light in the trends of medical teaching and practice." As one looks over pages and pages of prescriptions for complex nasty mixtures such as were inflicted on patients by eminent practitioners of the past, which are still reverently quoted and presumably used, one cannot help receiving the impression that our British confrères are even more conservative than the physicians in the United States. We feel rather happy that the "Favourite Prescriptions" in the *Practitioners Handbook* are by no means "favorite" in this country. In the foreword it is stated that "a sign of the present times is a diminution in polypharmacy and in the art of 'elegant' prescribing, which has coincided with and, it is to be hoped, is largely due to the scientific guidance of pharmacology towards really specific remedies." Unfortunately, with a few notable exceptions this book does not show this "sign of the present times." Nevertheless there are nuggets of gold hidden in the mass of rubble.

**Materia Medica, Pharmacology and Therapeutics.** By Maude B. Muse, R.N., A.M., Assistant Professor in Nursing Education at Teachers College, Columbia University, Second edition. Cloth. Price, \$2.75. Pp. 634, with 71 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This book is replete with excellent and practical information for nurses. The only question is whether it is not too complete. The policy of presenting to nurses pharmacology from the same standpoint as that taken in teaching medical students may be questioned. It is doubtful, for instance, that attempts at localization of the point of action of the nerve-muscle poisons will add much to the nurse's understanding of the subject, while necessarily causing her a good deal of grief in trying to memorize so many facts that are entirely unrelated to the practical use of drugs in her hands. Such warning, on the other hand, is apropos that the nurse oversteps her authority in withholding a dose of morphine when the physician prescribes it "p. r. n." and the overscrupulous nurse permits a patient to suffer pain all night. There are other such practical nursing precepts on the use of drugs in this book. It would have been well had the nomenclature of the new Pharmacopeia been more completely adopted, e. g., sulfate been written with f instead of ph. In spite of these criticisms, Muse's book is probably one of the best on the subject.

**Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Röntgenatlas früh-tuberkulöser Veränderungen im Hilus bei systematischen Standardqueraufnahmen.** Von Dr. R. Czarnecki, Leiter der Tuberkulose-Abteilung im Staatl. Gesundheitsamt Leipzig-Land. Fortschritte auf dem Gebiete der Röntgenstrahlen, Ergänzungsband LI. Herausgegeben von Prof. Grashey. Paper. Price, 24 marks. Pp. 98, with 308 illustrations. Leipzig: Georg Thieme, 1936.

As the name indicates, this is largely a book of illustrations showing the development of the primary tuberculosis complex, together with the subsequent secondary and tertiary lesions. The first part is a general consideration of the anatomy of the heart, bronchi and lymph nodes. The primary complex and the reinfection forms of lesions are described in the second half. Differential diagnosis is adequately treated, and there is also a discussion of treatment and classification. The remainder of the volume is devoted to illustrations and legends. Most of the illustrations are made from roentgenograms of the chest. In fact, in this series one is able to visualize almost every step in the evolution of tuberculosis in the human lung. A series of roentgenograms such as these represent, in an accessible form such as this book is, are invaluable reference material; hence, for the illustrations alone, this volume is worthy of a place in every physician's library.

**Osnovi patologichnoi fizologii. Tom drugiy. Za redaktsiyn O. O. Bogomolets.** [Principles of Pathologic Physiology. Volume II.] Cloth. Pp. 915. Kiev: Vydavnistvo vseukrainskoi akademii nauk, 1935.

The present is volume 2 of *Elements of Pathologic Physiology* edited by the Ukrainian Academy of Sciences under the editorship of O. O. Bogomolets. The volume contains chapters on the pathology of metabolism, fatigue, pathology of the endocrine glands, pathology of the nervous system, constitution and diathesis. The major part of the contributions are by the well known investigator academician O. O. Bogomolets and his talented co-worker N. B. Medvedeva. The text is abreast of the present status of our knowledge of physiologic problems besides containing considerable original matter. It speaks well for the high standard of scientific research of the Ukrainian Academy of Sciences.

**Elements of Electrocardiographic Interpretation, with Thirty-Eight Plates Illustrating the More Important Deviations from the Normal.** Selected from the Files of the Michael Reese Hospital. By Louis N. Katz, A.M., M.D., Physiologist and Director of Cardio-vascular Research, the Michael Reese Hospital, Chicago, and Victor Johnson, Ph.D., Instructor in Physiology, the University of Chicago. Second edition. Paper. Price, \$1. Pp. 39. Chicago: University of Chicago Press, 1936.

This booklet presents an outline of normal and abnormal electrocardiographic observations. The illustrations consist of well chosen electrocardiograms, which are clearly printed. The progressive electrocardiographic changes resulting from acute coronary thrombosis merit most favorable comment. An appendix contains a systematic outline of the procedure in reading an electrocardiogram. The booklet should be most useful to medical students and practitioners.

**Differentialdiagnose der Lungenkrankheiten mit besonderer Berücksichtigung der Tuberkulose.** Von Oberarzt Dr. med. P. G. Schmidt, Facharzt für Lungenkrankheiten und Chirurgie. Mit einem Geleitwort von Direktor Dr. H. Braeuning. Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose, Nr. 60. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, Dirigierender Arzt, Sommerfeld. Paper. Price, 18 marks. Pp. 182, with 109 illustrations. Leipzig: Johann Ambrosius Barth, 1936.

This monograph deals with a general consideration of the lungs and the various diseases that attack the lungs, bronchi and pleura. In addition to the more common diseases, almost all the rare conditions that involve the lungs, pleura and bronchial tree are presented and described. Special emphasis is placed on the finer points in differential diagnosis. Most of the illustrations are made from roentgenograms of the chest. In this series of illustrations virtually every disease in which the x-ray film is of value in diagnosis is illustrated. The text is presented in such a concise manner as to enable the physician to review the entire subject quickly.

**Manual for the Medical Services of the Peiping Union Medical College Hospital.** Revised by the Staff of the Department of Medicine. Edited by F. R. Dieulaide, Head of the Department. Fifth edition. Cloth. Price, \$1.50. Pp. 204, with 4 plates. Peiping, China, 1936.

No unusual features are presented in this compendium for the resident medical staff of a 350 bed teaching hospital. Much carefully selected information on laboratory, diagnostic and therapeutic procedures is incorporated in direct, concise language. Parasitology is emphasized.

- Metaphosphoric Acid in Extraction and Titration of Vitamin C. R. R. Musulin and C. G. King, Pittsburgh.—p. 409.

**Effect of Dextrose on Cholesterol in Blood.**—Sperry determined the concentration of total and free cholesterol in the blood serum before and after the administration of dextrose in healthy human subjects according to the technic of Fitz and Bruger. In contrast with their observation, no significant change in the proportion between the cholesterol fractions occurred. The result offers further evidence for the constancy of the proportion under physiologic conditions. Discussion of the apparent discrepancy with Fitz and Bruger revealed that they had employed highly abnormal patients as subjects; hence it is not possible to compare the results of the two investigations.

**Antirachitic Value of Irradiated Yeast in Infants.**

Drake and his co-workers found that the daily administration for five winter months of approximately 500 international units of vitamin D in the form of irradiated yeast to sixty-nine normally growing infants prevented the development in every instance of rickets of a moderate or marked degree. The daily administration of approximately 1,000 international units of vitamin D in the form of irradiated yeast to one infant

with marked rickets and of approximately 500 units to four infants with moderate or marked rickets brought about definite healing in the course of one month.

**Active Artificial Immunization in Diphtheria.**—Cooke summarizes the results of immunization against diphtheria in more than 500 young adult student nurses during a period of eighteen years, with the use of several types of antigens and with a variance in the number and spacing of the injections. A number of subjects immunized from six to sixteen years previously were retested to determine the duration of the immunity. Toxoid and especially alum-precipitated toxoid were relatively more effective than toxin-antitoxin. Two doses of toxoid or a single injection of alum toxoid immunized only 75 to 80 per cent. By far the best results were obtained by two doses of alum-precipitated toxoid, the second after an interval of several months, and by three doses of plain toxoid separated by intervals of several weeks. During the three years immediately preceding the adoption of immunization in 1918, seventy student nurses were on duty in the contagious wards and twenty of them developed clinical diphtheria. Since 1918 only two cases of diphtheria have occurred among almost 1,000 students, both in known nonimmunes, accidentally exposed to the disease before immunization. Of the 102 cases retested from six to sixteen years after immunization by toxin-antitoxin and subsequent negative Schick tests, more than 95 per cent were immune.

**Strangulation of Undescended Testicle.**—Strangulation of the testis is usually attributable to basic anatomic mal-development. In the case reported here by Woodruff and Milbert a long tongue of omentum completely encircled the mesorchium and strangulated the testicle and epididymis. Pathologically, the changes in the testis and epididymis depend on the degree of vascular impairment. Experimentally, irreparable damage is produced by vascular embarrassment of the testicle within twenty-four to forty-eight hours. The classic picture of acute torsion or strangulation of the testicle embodies a sudden onset, acute pain at the site, distention, nausea or vomiting, slight temperature elevation and peritoneal irritation. With the exception of some of the peritoneal irritation, this is the same syndrome that a patient with

## Current Medical Literature

**Increased Phosphatase Activity of Bone.**—The Gutmans and Sproul state that recent determinations of serum phosphatase activity in patients with cancer suggest that values obtained in cases in which there are widespread osteoplastic metastases are, in general, significantly higher than those found in association with osteolytic metastases. In the series reported by Gutman, Tyson and Gutman (1936) the serum phosphatase activity exceeded 10 Bodansky units per hundred cubic centimeters in six of ten cases with osteoplastic metastases, but in only three of nineteen patients with osteolytic metastases. In two patients with very extensive osteoplastic skeletal lesions, values exceeding 100 Bodansky units per hundred cubic centimeters of serum were obtained, as contrasted with the normal maximum of 4 Bodansky units. The rise in phosphatase activity of the serum in such cases is the result of increased elaboration of phosphatase, which is subsequently released into the circulating fluids. Direct evidence in support of this assumption is afforded by the present investigation, which disclosed strikingly increased phosphatase activity of bone at the site of osteoplastic skeletal metastases in a patient with carcinoma of the prostate

gland. The mechanism of bone formation in metastatic osteoplastic neoplasms is fundamentally the same as that of normal bone formation. The capacity to stimulate production of phosphatase may play an important part in determining the osteoplastic character of the metastatic bone lesions observed in association with certain neoplasms. Chemical studies tend to support the views of pathologists who have long postulated the elaboration by certain tumor cells of a chemical factor initiating bone formation in osteoplastic metastases.

\*Effect of Thyroid Therapy on Mental and Physical Growth of Cretinous Infants. A. Gesell, Catherine Strunk Amatruda and C. S. Culotta, New Haven, Conn.—p. 1117.  
**Effect of Thyroid Therapy on Cretinous Infants.**—Gesell and his associates have assembled data on six cases of cretinism or hypothyroidism in which the condition was recognized and treated adequately in infancy. Physical and mental observations are presented in close association. They formulated the mental observations quantitatively by using the Yale norms of infant development. Extensive cinema records also served to place the data on mental growth on an objective and quantitative basis. The effects of thyroid substance on the cretinous infant are metabolic or dynamic, somatic and neurodevelopmental. The metabolic effects, which involve the vegetative system and the dynamics of behavior, are the most immediate and general. Marked physical improvement occurred in the six patients, with development of a normal appearance and acceleration in physical growth, particularly in the length of the legs. The mental status under treatment varied widely, from persisting severe mental deficiency to normal intelligence. Every cretin has a latent and distinctive optimal response, which is probably favored by early treatment. The ultimate response can be forecast by repeated careful determinations of physical growth and of behavior status during the early months of treatment. The therapeutic effects of thyroid substance depend on factors of biochemical readiness in the organism. The primary effect is on the thyroid itself and on associated glands, enabling them to resume their regulatory functions. The final influence on the cretin is contingent on the residual physiologic capacity and the latent growth potency of his neuro-endocrine system. Thyroid therapy cannot bring about normality if there has been a fundamental impairment of that system, hereditary or developmental. The initial response to treatment cannot be determined fully without a diagnosis of the behavior status. The development of the central nervous system can be tested only by an appraisal of the infant's behavior patterns.

**Surgical Treatment of Multiple Sclerosis.**—Flothow discusses the rationale of the treatment of multiple sclerosis by cervicodorsal sympathectomy. Recent studies on the pathogenesis of the disease indicate that the sclerotic plaques are in some way related to blood vessels and it is therefore possible that the disease is due to an inadequate blood supply to the central nervous system. By surgical resection of the sympathetic nerves it is felt that the blood supply to the brain and spinal cord is improved and that this may result in at least checking the progress or even improving the symptoms. A series of eighteen cases, ten women and eight men, is reported, in which sympathectomy has been performed. The results have been good in five men of the first six cases done, and in three of these five the results are considered excellent. The other two cases are too recent to make a prognosis. The results in women have been excellent in two cases and in two others sufficiently good to warrant the procedure. In the remaining six cases, apparently no benefit was obtained.

**Efficiency of Sand Filters in Removing Amebic Dysentery Cysts from Water.**—Baylis and his co-workers conducted experiments on the removal of *Endamoeba histolytica* cysts from water by rapid sand filtration and found this method effective. The filter used in the experiments had a surface area of 10 square feet and contained 24 inches of sand having an

effective diameter of 0.5 mm. The cysts were not in the water when it was coagulated but were added to the coagulated water going to the filter. They were fed into the influent water at a constant rate from 5 gallon portions of a suspension of the organisms. The number of cysts in the influent water varied from 362 to 2,370 per gallon of water. A total of 114 gallons of filtered water was tested and only four cysts were found. The percentage of reduction was in excess of 99.99. The duration of an experiment was from 3.7 to 13.7 hours. From nine to seventy-four liters of filtered water was collected at equal intervals during the period of the run. The filtered water collected for testing was first run through a Foerst centrifuge for concentrating the cysts. Prechlorinating the water did not affect the efficiency of the filters.

**Reagent for Detection of Vitamin B<sub>1</sub>.**—Prebluda and McCollum found that when a solution of *p*-amino acetanilid or methyl-*p*-amino phenyl ketone (*p*-amino acetophenone) is treated with nitrous acid and the resultant product is treated under certain conditions with vitamin B<sub>1</sub> there is produced a characteristic purple red compound which is stable and highly insoluble in water. The solutions of the treated amines will not react under these conditions with any substances as yet tried to form the same characteristic insoluble compounds which are colored. The colored vitamin-reagent compound may be extracted by means of a suitable selective solvent. Such a method may afford means of concentrating vitamin B<sub>1</sub>. Since the coloration is of a permanent nature, it provides a method for the quantitative as well as qualitative estimation of the vitamin. Determinations may be made within several millionths of a gram of the active material.

**Postural Syndrome and Obesity.**—Kerr and Lagen discuss a type of obesity that appears to be exogenous in origin, arising in persons whose dietary habits lead to a caloric intake beyond their daily requirements. It is not easy to determine whether individuals with the relaxed habitus are predisposed to the train of events which follow, but it is apparent that, when medical attention is sought, these patients present the posture of relaxation. The gradual accumulation of adipose tissue in the normal depots for fat gives the appearance of rotundity usually designated as corpulence. The accumulation of fat in the third decade is relatively symptomless. In the fourth decade the appearance of the individual is one of increasing corpulence, with a tendency toward a florid complexion. The normal curves of the spine are accentuated. The added weight of fat of the abdominal wall and viscera moves the line of gravity forward, and to compensate for this the major portion of the thorax is moved backward, accentuating the lumbar curve. The upper part of the thorax and shoulder girdle move forward, increasing the normal thoracic curve; and the head and neck are thrust forward as is required for adjustment at a new line of gravity. The fifth decade marks the period of transition from the state of physical well being and activity of youth to one of gradual lessening of activity of middle and old age. The syndrome itself is certainly modified or delayed in susceptible individuals by proper exercise and diet. Heredity may be a factor in its development, as shown by the familial occurrence of arteriosclerosis, arthritis, premature gray hair and particularly corpulence. Environment is related directly. The condition singles out individuals of sedentary occupation. The most obvious result is the gradual development of a heavy, pendulous abdomen. The respiratory and circulatory manifestations are primarily due to interference with proper ventilation of the lungs based on postural defects and the disadvantages under which the diaphragm functions under the circumstances. The orthostatic dyspnea, reduced vital capacity and tidal air, polycythemia and cyanosis are closely related. In older subjects hypertension, systemic and pulmonary, and arteriosclerosis account for definite cardiac complications. Treatment requires temporary support for the pendulous abdomen and assistance in the evacuation of the lungs during expiration. A belt gives this support and aids in expiration. The weight should be gradually reduced to correct the distortion of the spinal axis and restore the spinal curvature. Postural training is of greater value after the adipose tissue has been reduced but is of little value in the patient with a pendulous abdomen and a great counterweight of visceral fat that interferes with the ascent of the diaphragm during expiration.

**Histidine Hydrochloride in Treatment of Peptic Ulcer.**

—Eads gives a follow up of eighty-five cases of peptic ulcer in which treatment was given with daily intramuscular injections of a 4 per cent solution of histidine hydrochloride. Forty-five of the patients have been followed for a period of about eighteen months, and forty for a period of six months. He has found that, although the immediate results secured by histidine hydrochloride therapy may be generally favorable, the effect is not continuous in a large percentage of cases. The mechanism by which histidine therapy produces benefit in patients showing immediate improvement is not explained satisfactorily. Some of the favorable effects may be psychic. As other observers

have found, the immediate results obtained in the use of histidine hydrochloride are excellent in a large number of cases of uncomplicated peptic ulcer. However, their end results after fairly short observation periods are not as good as those following the orthodox medical treatment. Histidine in the treatment of peptic ulcers has its place, for in many cases relief of symptoms is so prompt and so spectacular that this immediate effect alone would justify its use. Histidine hydrochloride therapy cannot supplant the dietary-alkaline medical treatment, but it may be a valuable addition to this treatment, particularly in cases which do not respond readily to the orthodox measures. In cases in which further surgery is contraindicated, histidine therapy offers aid.

**Aleukemic Reticulosis.**—Wayson and Weidman cite a case of aleukemic reticulosis in which there was a preliminary itchy diffuse dermatitis lasting five months; after a remission resulting from treatment, it recurred in a modified form in four months. Symptoms of pulmonary tuberculosis were recognized at the eleventh month. At the twelfth month a nonpruritic dermatitis developed. At the thirteenth month a moderate adenopathy and splenomegaly were detected. The tumor stage developed at the thirteenth month, after which the remaining course of the disease (nine weeks) was fulminating, consisting of marked emaciation, fever, severe symptoms in the joints and death. Roentgen studies demonstrated disease in the bone marrow with infiltration and destruction of bone—a point that may be of some diagnostic value in cases of similar disorders in the future. These observations were confirmed at necropsy, after which microscopic examination of tissue referred the proliferative processes to the reticulo-endothelial system. Since there was no leukocytosis, the disorder may be classified as an aleukemic reticulosis. With two important exceptions this disorder closely parallels the leukemic reticulosis (monocytic leukemia) studied by Mercer and Loveman—the clinical course was rapidly fatal, the adenopathy was not extreme and the cytologic picture was similar. The lesions were dusky or bluish red; this remains to be determined as a generality. By contrast with leukemic reticulosis, the disorder produced lesions of the order of tumors and did not produce a leukocytosis.

**Monocytic Leukemia and Reticulo-Endotheliosis.**—Lynch has seen a number of cases of monocytic leukemia and reticulo-endotheliosis. Monocytes observed in leukemic blood may develop directly from the reticulo-endothelial system in a manner related to the normal or in myeloid tissue as a development from the myeloblast. In the first type there is reticulo-endothelial hyperplasia with mobilization of the cells into the blood and differentiation to monocytes (Schilling type). In the second type the pathologic picture in the tissues is that of myelogenous leukemia, while myeloblasts and other immature granulocytes as well as immature and mature monocytes are present in the blood (Naegeli type). The clinical and microscopic observations in eight cases of monocytic leukemia and reticulo-endotheliosis associated with cutaneous changes are described. The difficulties in the clinical diagnosis of general-

Surgical Clinics in Scandinavia. A. R. Short.—p. 157.

**Treatment of Sciatica.**—Short points out that sciatica is only a name for a group of symptoms, and before it can be treated rationally one must know what is the underlying cause. Sciatica is seldom bilateral; if it is, the cause will probably be some definite disease, such as a pelvic tumor or a growth of the spine or spinal cord. Sciatica may be associated with lumbago. The physical signs are sometimes, especially in early cases, absolutely negative, but as a rule one can elicit tenderness on deep pressure on the buttock over the point of emergence of the nerve through the sacrosacral notch, tenderness along the nerve trunk down the back of the thigh and over the external popliteal nerve where it crosses the fibula, and pain when the knee is extended with the thigh flexed. No one cause will explain every case of sciatica. Sciatica may be classified into the following groups: the fibrositis group, pelvic growths, growths of the spine or spinal cord, sciatica with lumbar scoliosis, sacro-iliac disease and an unexplainable group. The author's experience is confined to three cases in which division of a tense fibrous band pressing on the sciatic nerve proved sufficient. In the first case the point of exit of the sciatic nerve was approached by Crawford Renton's incision with transection of the fibers of the gluteus maximus, in the other two by splitting that muscle directly over the nerve in the line of its fibers. A tense band was felt closely applied to the antero-external side of the sciatic nerve in the three cases. The operation is not called for until the simpler and generally recognized methods of treatment have been tried and have failed. It begins to be indicated for the intractable cases in which no definite cause is found, and particularly when there is definite wasting of the muscles supplied by the external popliteal nerve. It is not to be regarded as a cure-all; it will succeed only in cases of sciatica, probably a minority, in which the pain is due to the band pressing on the nerve.

**Chronic Diffuse Bronchopneumonia.**—Scadding presents three cases that were characterized by a subacute to chronic course, the duration of symptoms from onset to death being

two years, seven months and three and a half months, respectively. Cough was an initial symptom in all cases; it was accompanied by sputum which, at first scanty and mucopurulent, gradually increased in amount and became frankly purulent. Small hemoptyses occurred in all cases. Dyspnea was prominent and was steadily progressive. Pleurisy was a feature of cases 2 and 3, followed by a clear, lymphocytic effusion in case 2, and by purulent effusion in case 3. Fever and parallel increase in pulse rate were present; the fever was not very constant. During the earlier stages of case 1 only slight or no pyrexia was present, but a rather marked diurnal swing was observed. In the terminal stage of this case the pyrexia was sustained. In cases 2 and 3 an irregularly swinging pyrexia was observed throughout. Roentgenologically, the common factor between the three cases was the presence of mottling of such a type as to suggest tuberculous infiltration. The increase of this mottling in the chronic case 1 and the acute "wholly" spread to the left middle zone observed in the more acute case 3 form interesting parallels to the similar changes observed in the progressive course of pulmonary tuberculosis. Pathologically, the essential lesion in each case was simple pneumonia in varying stages of evolution. The only unusual features were the diffuse distribution of the lesions through both lungs and the presence in different foci of all stages of pneumonia—early consolidation, resolving consolidation, organization and suppuration. A correlation of the clinical, roentgen and necropsy observations suggests that the underlying pulmonary lesion was essentially a diffuse bronchopneumonia in rather small foci, showing an unusual variety of modes of progress and spread, progress being toward resolution in some foci, toward organization leading to fibrosis in others and toward suppuration leading to minute abscesses in others; spread being not only by local extension but also, on the evidence of roentgen examination in cases 1 and 3, by the appearance of fresh foci in previously unaffected areas of lung. Consideration of the cases reported and of the similar cases collected from the literature leads the author to the conclusion that there is a group of cases of chronic diffuse bronchopneumonia which may form a recognizable clinical entity. Its clinical and roentgen manifestations closely resemble those of some forms of pulmonary tuberculosis, and it is from the latter condition that differential diagnosis is most important.

**Variations of Blood Pressure in Diseases of Hypophysis.**—Marañon and Domenech say there is no proof that the hypophysis or its diseases influence the blood pressure in any way. The opinions of some of the principal investigators on the subject differ widely. The high pressure of the basophil adenoma may be explained by a concurrent hyperfunction of the adrenals; the low pressure of hypophyseal cachexia by the coincidence of other lesions—probably the most frequent would be adrenal insufficiency—and, above all, a very poor general condition. The behavior of the blood pressure in other hypophyseal symptoms has no influence on the blood pressure, since states both of hyperfunction and of hypofunction of the anterior and the posterior lobes have no connection with uniform changes in blood pressure. The variations of pressure observed are merely the normal changes observed in any other group of patients and are clearly due to causes that have nothing to do with lesions of the hypophysis. It will be observed that the higher pressures, in each of the diseases under study, generally correspond to older patients. The pressures for the average age coincide with the average figures for that age, independent of the disease. In addition, with a few exceptions the highest pressures in isolated cases are in part explained by the concurrence of hypertensive vascular lesions, especially arteriosclerosis.

hepatic edema was present four times. Five of nine cases of thrombocytopenic purpura presented hepatic edema. The relatively high incidence of hepatic edema in cases of death following burns seems to conform with the observations of Eppinger. However, death occurred soon after the accident in only two cases. In only three cases in which death occurred subsequent to operation were the clinical criteria of shock satisfied and in these cases hepatic edema was not found. In three of seven cases of acute coronary occlusion terminating fatally with the picture of shock, hepatic edema was present. The most conspicuous hepatic edema was observed in two cases of unexplained death which were investigated by the medical examiner of New York City.

**Treatment of Sexual Underdevelopment in Boys.**—During the last four and a half years Sexton treated eighteen boys in whom the testes were not definable in the scrotum with gonadotropic substance of pregnancy urine. Six of the eighteen were complicated by hernia and three of these had been operated on previously, and the unsatisfactory operative results precluded any result from organotherapy. Of the remaining fifteen cases (twenty instances) complete descent occurred in ten cases (fifteen instances) and incomplete descent (intermittent retraction into canals) in two. It is believed that, in those instances in which testicular tissue is not definable in any part of the genital tract, true cryptorchism does not necessarily exist. Instead there is rudimentary testicular tissue that cannot be differentiated from other soft tissue. On the average, treatment totaling 4,800 rat units of gonadotropic substance of pregnancy urine over a period of eight weeks should suffice to determine whether or not results are to be expected. Boys with obesity, of the pituitary types, responded more favorably than those of the eunuchoid types. Treatment of subnormal genital development was less effective than the treatment of nondescent. Delayed descent results in abnormal physical proportions with predominating excessive growth of the long bones. Surgery is recommended for all cases complicated by hernia and those in which organotherapy fails.

**Subclinical Hypothyroidism in Children.**—To determine the incidence of mild cases of hypothyroidism, Molitch and Poliakoff investigated the inmate population (514) of the New Jersey State Home for Boys. The ages of the boys

ranged between 8 and 17 years. The entire group was roentgenographed and those with delayed carpal development were studied in more detail. Total serum cholesterol determinations were made on the entire group, and norms were developed. Those with retarded osseous development and those with high cholesterol were given basal metabolism tests. The observations were then correlated with psychologic data, behavior and school achievement and were checked against the opinions of eleven well known endocrinologists, obtained by the questionnaire method. The results indicate that osseous retardation is the most consistent finding in hypothyroidism in children; fifty-four in the present series. Basal metabolism and serum cholesterol studies are of little aid in the diagnosis in children, because of variability and lack of consistent relationship to the clinical pictures. In the clinical picture only dryness of the skin and the brittleness of the hair were found consistently. A history of overweight at birth and a delay in development, such as teething, walking and talking, is of corroborative significance. The intelligence is not a reliable criterion: some hypothyroid children are bright and some are retarded. The behavior was found to be either hypo-active or hyperactive and hence of little aid in the diagnosis. Subclinical types of hypothyroidism may be recognized by the osseous retardation as revealed in the roentgenogram and by the favorable reaction of the patient to replacement therapy with thyroid substance.

**Sensitization to Mosquitoes.**—Benson presents the case histories of four patients who exhibited lesions due to the bites of mosquitoes. On repeated occasions the patient's arm, subjected to the sting of confined mosquitoes which had been hatched in the laboratory, developed typical immediate and delayed reactions, while normal controls, under the same conditions, showed no noteworthy deleterious effects. Simple buffered-saline extracts and concentrated extracts by precipitation with ammonium sulfate or, more often, cold alcohol or acetone gave strong specific reactions by intracutaneous inoculation in the sensitive patients and but little in the numerous normal controls. The concentrate gave uniformly larger reactions than the simple extract. Reinoculation of extract from the same or another species of mosquito in a former site two or more days after the first inoculation showed abolition of the late reaction, but not of the early wheal. This raised the question of a possible multiplicity of antigens. A relatively small number of injections desensitized three of the four patients treated, all of whom had been extremely reactive to the stings of mosquitoes.

**Reactions to Tuberculin in Secondary Syphilis.**

Flandin and his co-workers attempted to determine the conditions that affected the cutaneous reactions to tuberculin in syphilis in comparison with other skin tests. The skin sensitivity to tuberculin was investigated in all their patients by means of cutaneous reactions and intracutaneous tests with tuberculin diluted 1:100. In the instances in which these reactions were negative, the results were controlled by tuberculin diluted 1:10. There were forty patients in their series, divided into three with primary syphilis, twenty-eight with secondary syphilis and nine with tertiary syphilis. The cutaneous and intradermal reactions were positive in all the patients with primary syphilis, in seventeen of the twenty-nine patients with secondary syphilis, and in six of the nine patients with tertiary syphilis. In interpreting these reactions, it is necessary to remember that variations in the reactions of the skin to tuberculin do not permit a priori conclusion as to the allergic modification of other tissues. Nevertheless, three points emerge from these studies: in all cases observed to give negative skin reactions there were florid mucous cutaneous syphilids; the specific treatment seemed to have a manifest influence on the evolution of these cutaneous reactions, and the rapidity with which these reactions varied was noteworthy. The mode of reaction of the skin to other tests, such as the histamine test, was also observed. No correlation could be determined, however, between the intensity of the skin reaction to histamine and that to tuberculin.

\*Early Gastroscopic Diagnosis of Antropyloric Cancer. R. Chevallier.—p. 719.

**Gastroscopic Diagnosis of Antropyloric Cancer.**

According to Chevallier, the usual methods of examination do not allow the truly early diagnosis of cancer of the antropyloric region in the majority of cases. Operative control shows, in fact, that often the infiltration of the antral walls is advanced before the clinical symptoms, x-ray appearances or laboratory examination furnish any presumptive signs. Gastroscopy, on the contrary, in spite of certain difficulties of interpretation, seems to be undoubtedly the procedure of choice for demonstration of the initial aspects of malignant degeneration in this region. The endoscopic pictures which the author reproduces and discusses show all the early signs of cancerous infiltration. He believes that all the facts found can be grouped under one formula, consisting of a leukocytic and atrophic alteration with absence of mucous secretion of the antrum. An associated anatomic state exists with diffuse atrophy similar to that which is sometimes observed in pernicious anemia. This endoscopic syndrome, which the author has never seen in the absence of cancer, should be systematically searched for in all cases of gastric disease of the adult in which the cause is not rapidly discovered. Furthermore, discovery of this syndrome is one of the most important indications for exploratory laparotomy.

**Mushroom Poisoning and Rechlorination.**—Le Calvé reports the illness of nine monks, from 21 to 62 years of age, following a meal containing a considerable quantity of poisonous

mushrooms (*Amanita phalloides*). Eight hours after their meal, one of them became ill with epigastric pain, vomiting and diarrhea. During the next four hours the signs of intoxication appeared in the other eight. In all, the poisoning was manifested by an initial phase with colic, increasingly frequent mucous stools, incessant vomiting and absolute intolerance of the stomach to ingested substances. The monk who first became ill died on the third day. The author gave the others cold water to which salt had been added and after a short time the patients were able to retain the solution. The effect was almost immediate. Vomiting ceased, and the critical situation of some of the monks changed immediately. Recovery progressed rapidly, and all the remaining monks survived in apparently good health. Rechlorination thus becomes an important indication in mushroom poisoning.

**Cevitamic Acid and Carbohydrate Metabolism.**—Dessy and Catagni studied the behavior of cevitamic acid on the metabolism of carbohydrates in normal persons and in those suffering from diabetes mellitus. The intravenous injection of from 0.05 to 0.3 Gm. of cevitamic acid increases glycemia in normal persons who are on a normal diet and decreases it in patients suffering from diabetes mellitus and avitaminosis C. In normal persons and in diabetic patients who for several days have been on a diet without vitamin C the glycemic curve, following oral administration of 150 Gm. of dextrose, does not change if an intravenous injection of 0.25 Gm. of cevitamic acid is given simultaneously. The oral administration of 150 Gm. of dextrose produces hyperglycemia, which is higher if the persons receiving it are given a diet without vitamin C. The simultaneous administration of insulin and cevitamic acid increases the duration but not the intensity of the hypoglycemic reaction to insulin in normal persons. In some diabetic patients it inhibits the action of insulin (no hypoglycemic reaction is produced). In other cases hyperglycemia follows the combined insulin-cevitamic acid injection. When administered alone in diabetes mellitus, it produces hypoglycemia. Its hypoglycemic action, however, does not strengthen that of insulin. It seems that the mechanism of action of each substance on the regulation of glycemia is different. Insulin induces the utilization of dextrose by the tissues, whereas cevitamic acid acts on the vessels.

**Phenols in Blood in Renal Diseases.**—Castex and Arnaudo determined the amount of phenols in the blood of patients suffering from renal diseases with renal insufficiency and also in patients suffering from insufficiency of the right half of the heart. They believe that the intensity of phenolemia in renal diseases depends on the intensity of renal insufficiency. The presence of high hyperphenolemia corresponds to grave renal insufficiency. In cases of chronic and acute glomerulonephritis there is moderately increased phenolemia, as a rule, although in some cases it may be normal or exceedingly high. It is normal in patients suffering from hypertension in renal diseases if the function of the kidneys is well preserved. The amount of phenols in the blood of patients suffering from renal diseases of different nature (polycystic kidney, renal tuberculosis and lithiasis) is regulated by the renal function. Right cardiac insufficiency is associated with normal phenolemia or with moderate hyperphenolemia which is greater during the periods of anuria. Hyperphenolemia is generally associated with anuria.

strangulated hernia would present. With a history of undescended testicle and the presence of a tender swelling in the groin, one must immediately suspect a vascular insult to the organ. Differential diagnosis lies among an acute epididymo-orchitis, acute inguinal adenitis, strangulated hernia, a strangulation of the testis or torsion of the cord. Once a diagnosis has been made, surgical intervention should be directed at removal of the involved organ and also to correction of the hernia, potential or actual, which is almost always present. Some favor the conservative course, when pain and systemic reaction is not a factor, feeling that an atrophic testis is better than none at all.

**Elimination of Physiologic Error in Phenolsulfonphthalein Test.**—Blasucci points out that the phenolsulfonphthalein output in arbitrarily fixed periods of time is an expression of kidney function carrying in itself an irremovable error (33 per cent), for which the kidney cannot be held responsible. It is possible to avoid this error by a comparison based on the "total limit output" and not on the injected quantity. The proportion between the output in a given time and the total limit quantity gives an extremely exact idea of the kidney's functional value. Sodium hydroxide is added and both the initial and residual samples are diluted with water and urine until the tone and quantity of color are identical in the two samples and then filtered. The residual limit sample is fixed at 10 mm. in any Duboscq type colorimeter and compared with the initial sample. The reading of this is usually 3.3 mm. and may vary from 3 to 4 mm. in normal kidneys, but no more. The smallest renal lesion will immediately bring this reading to 5, 10 or 20 mm. and in severe cases to 60, 100 mm. and even more. The proportion is read directly on the colorimeter and no calculations are required. The error most to be feared and prevented is the remaining of color in the pelvis and ureter dilated by back pressure. Forcing fluid helps prevent this source of error.

**Human Bite Infection** eighteen cases of human bite Massachusetts General Hospital usually present in such an anaerobic Vincent's organism determination of prognosis within the joint, (2) the type length of time before surgery series of eighteen cases, six in five of fifteen operative of fingers. Diathermy excision in early cases. Primary From a review of all reported case out of ten will require

1931 and 1935 the author concludes that a localized partial thoracoplasty, planned so as to correspond to the size and location of the cavity, is the operation of choice. It can take the place in the great majority of cases of the more formidable total paravertebral thoracoplasty. It is to be preferred to the operation of paraffin plugging in cases not restricted by the patient's general condition to a minimum intervention. Like the former operation, partial thoracoplasty need not be limited to one side. Stereoscopic roentgen presentations demonstrated that a satisfactory collapse of the apical region can be accomplished only with the widest possible resection of the first two upper ribs. He has demonstrated that old, stiff-walled cavities could be made to heal by a partial thoracoplasty. The danger of aspiration pneumonia was no greater than that with total thoracoplasty. The author reports 207 partial thoracoplasties with a mortality rate of 7 per cent. There were fourteen instances of aspiration pneumonia with eight fatalities. The mortality in 1935 (fifty-seven operations) was 2 per cent; 63 per cent of the patients were rendered free from tubercle bacilli in the sputum, 21 per cent were returned to work, 29 per cent were improved and 6 per cent were made worse.

**Heat Therapy in Surgery.**—Karitzky observed the spontaneous sweating of patients on the operating table or of patients in shock. The postoperative sweating ceases when the patient has recovered from operative trauma. Sweating while on the operating table is not due to the temperature of the air surrounding the body of the patient but to circulatory, respiratory and metabolic alterations produced by the operative trauma, anesthesia and shock. The author demonstrated that blood acidity and hydrogen ion concentration of the sweat secretion are interdependent. Inhalation of oxygen had the effect of terminating the sweating process. The method employed to induce sweating was to place between the blankets that covered the patient a number of electric bulbs sufficient to raise the temperature to from 60 to 80 C. This was kept up for twenty minutes when the lamps were removed. The body loses from 500 to 800 cc. of water during a sweat bath lasting one-half hour. To make up for the loss the patient is given 1,000 cc. of Ringer's solution by hypodermoclysis before the application of heat therapy. Patients in a grave state are given an intravenous drip of 5 per cent solution of dextrose. The entire process may be repeated two or three times within twenty-four hours. Achelis has demonstrated a lowered alkali reserve of the blood at the end of an operation. After ether narcosis it returns to normal four hours later; in the presence of a damaged liver, from eight to twelve hours later. The lactic acid blood content was found to be diminished after the sweating. Barcroft and Rein showed that the effect of heat on the skin was to accelerate the circulation of blood. The effect of heat therapy and sweating on the vegetative nervous system manifested itself by two phases. In the first there was lowering of the blood pressure, sinking of the blood alkali reserve, increase in the lactic acid blood content and depression of respiration. The second phase manifested itself by loss of acidity of the blood, leukocytosis, rise of blood pressure, accelerated circulation, faster pulse, deeper breathing and a sense of well being. There were no deleterious effects noted following this therapy in 300 patients thus treated in the surgical clinic of the University of Freiburg. The method was found to be most valuable in acute pancreatitis, intestinal paralysis and diffuse suppurative peritonitis.

\*Cure of Case of Severe Hemorrhagic Colitis by Estrogen. R. Korbach.—p. 1602.

**Significance of Stippled Cells Appearing After Administration of Potassium Iodide.**—Böhm and Fellinger point out that in persons who have recovered from lead poisoning the mobilization of an old lead depot may result in the reappearance of stippled cells. Reappearance following treatment

with potassium iodide has been interpreted as a definite proof of a former lead intoxication. In order to determine the reliability of this test, the authors subjected normal persons and patients who had had lead poisoning to the so-called potassium iodide provocation test and found that even normal persons may show considerable numbers of stippled erythrocytes (five of twenty-four persons). Moreover, almost half of the patients failed to react with stippled cells to the potassium iodide provocation. The authors conclude that the test is not sufficiently reliable for the diagnosis of a former lead intoxication. To be sure, if a positive provocation test concurs with several other symptoms indicative of lead intoxication there is some probability, but the outcome of the test cannot be regarded as decisive.

**Estrogen in Hemorrhagic Colitis.**—Korbach directs attention to the concurrence of gastro-intestinal disorders with ovarian dysfunction and reports the clinical history of a woman, now 30, who was under his observation for seven years. Following treatment of an anal fissure at the age of 23, she developed proctitis, which soon became hemorrhagic. The bacteriologic examination of the erosions as well as a search for amebas remained negative. Various dietetic measures, irrigations, blood transfusions and other treatments failed to cure the disorder. On account of loss of considerable blood the prognosis seemed unfavorable until the cessation of the disorder in the course of two pregnancies suggested a new treatment; namely, endocrine therapy by means of estrogen. The first two injections of 100 mouse units each produced a noticeable change, and after four more injections of 2,000 mouse units each the rectal mucous membrane became normal again. Moreover, this treatment counteracted the existing frigidity and improved the general condition.

**Roentgenotherapy of Angina Pectoris.**—Gilbert shows that the roentgenotherapy of angina pectoris, in order to be effective, must be directed against the functional disturbances. The destructive action of the roentgen rays is not desired, nor is it the aim to effect anatomic changes; on the contrary, efforts are made to avoid such changes. Clinical experiences and experiments have proved that roentgen rays exert an influence on the sympathetic nervous system and the author thinks that it is this action of roentgen treatment which is responsible for the effects that develop without demonstrable histologic changes. As examples of such effects he mentions the results of the irradiation of the thyroid in exophthalmic goiter and of the irradiation of the ovaries with small doses in cases of amenorrhea or oligomenorrhea. He discusses the theories that try to explain the mode of action of the roentgen rays in these conditions. He thinks that they influence particularly the neuro-endocrine system. His own observations were made in ten clinically proved cases of angina pectoris. He obtained improvement in five; in two the improvement has persisted for from nine to ten months. He recommends roentgen treatment for patients in whom the condition has become stationary. The rays should not be applied during the attack. The aim of the treatment is to reduce the number and the intensity of the attacks or to counteract them entirely. Roentgen therapy is contraindicated in patients with cachexia, with considerable cardiac insufficiency and in those more than 70 years of age. The technic differs with the various authors. Equally good results have been obtained with rays of moderate and of considerable hardness. The rays are usually applied in the cardiac and the paravertebral regions. He uses 180 kilovolts, from 0.7 to 1 mm. of copper with 1 mm. of aluminum, 4 milliamperes and a focus skin distance of 50 cm. He employs small doses, realizing that large doses may cause exacerbations. He usually begins with a surface dosage of 40 roentgens, in order to test the sensibility of the patient. Later he increases the doses to 50 and 75 roent-

aids in localizing the infection; if its response is inadequate, systemic invasion may occur. 2. The formation of specific immune bodies is stimulated by Bacterium tularensis, agglutinins apparently persisting indefinitely. This patient's lymphatic system responded by marked enlargement of the epitrochlear and axillary lymph nodes, and, since there was no evidence of invasion of the lungs or mediastinal lymph nodes in a roentgenogram of the chest five months after infection, this defense was apparently sufficient to limit the process to the left arm and left breast region. The agglutination titers dropped from a recorded 1:320 at five months to only 1:40 at twenty-one months; even though the organism was still virulent. The patient's tularemic agglutination decreased while the syphilis responded well both clinically and serologically to treatment. It seems unlikely, therefore, that the course of the tularemia was influenced adversely by the concomitant syphilis. However, the effect of the tularemia on syphilis is interesting in that presumably syphilitic "recurrent secondaries" occurred after the tularemia inoculation. The case lends support to the theory recently advanced by Foshay and Mayer that the continued presence of specific agglutinins in tularemia results from the prolonged existence of the organism in the body acting as the antigenic stimulus. The pathogenicity of the bacterium appears to be influenced over a long period by ability of the body to combat the disease with specific immune bodies.

**Peritoneal Response to Surgical Glove Powder.**—Small foreign body granulomas were produced experimentally by Owen in the peritoneal tissue of rabbits that were identical, grossly and histologically, to the granulomas removed from the peritoneal surfaces of the intestine and ovary of a young woman two years after appendectomy. The peritoneal tissues of experimental rabbits reacted in essentially the same manner to the powder commonly used in preparing surgical gloves, as did the peritoneal tissues in the case reported. The reaction consisted of cellular proliferation and the formation of small foreign body granulomas. It is probable that the small nodules found on the surfaces of the cecum and colon had some influence on the symptoms of which the patient complained: cramping abdominal pain, nausea and vomiting, constipation and bloating. At the time of the second operation the surgeon did not find

sufficient adhesions to account for all the patient's symptoms. Powder should be removed from the surface of gloves before operation, either by careful cleaning with a towel or by washing in sterile solutions.

**Care of the Feet in Diabetes.**—Jordan believes that gangrene in diabetes is preventable in many, if not most, cases. The application of simple rules of hygiene and the prompt and correct surgical treatment of each lesion when it first appears will postpone or prevent disastrous situations. Regular visits by the patient for examination, treatment and instruction by the physician tend to prevent trouble. Cleanliness, correction of preformed defects and immediate attention to all lesions will prevent or at least postpone severe infection and gangrene. A corn and callus by pressure causes local irritation and ischemia so that necrosis and infection may occur. Similarly a bunion or hammer toe increases the danger of infection. Epidermophytosis with coarse nails and soft corns leads to many amputations. In addition to the daily bath, thorough drying and clean socks, one must often employ other methods to combat this stubborn disease. The liberal use on the feet and in the shoes of talcum containing 1 per cent of salicylic and benzoic acid is sometimes adequate. When a stronger remedy must be used, the daily application of a petrolatum ointment containing 6 per cent each of salicylic acid and sulfur should be continued until there is apparent cure of the disease. It is important to apply this not only on all obvious lesions and between and under the toes but also around the entire nail bed. After the disappearance of the lesions, applications should be continued indefinitely twice a week to prevent recurrence. It is a good rule for all diabetic patients to refrain from crossing the legs after they attain the age of 40 years. Constriction of any kind should be avoided. Exercises are of help in maintaining or restoring circulation. In instances of deficient circulation or damaged nerves, all irritants, hot water bags, electric pads and iodine or other chemical irritants are interdicted. Prevention and care of foot ailments in diabetic patients are dependent on control of the diabetes. The blood and urine sugar must be controlled, and also the diet must be sufficiently liberal to maintain good health.

blood transfusions employing the continuous drip method in twenty-five patients. The method makes it possible to transfuse acutely anemic patients with massive doses of blood without embarrassing the cardiovascular system. Its advantage over the former method is that it permits the slow introduction of blood. The effect of continuous drip infusion manifested itself as an immediate replacement therapy as well as an activator of the hematopoietic activity. Massive transfusions are indicated in resistant anemic states with a markedly lowered regenerative capacity, as a preoperative measure, and in conditions in which replacement of blood in a given time is required in a bleeding patient. The therapeutic effect obtained is not always proportional to the amount of blood introduced. The hematologic response to the same quantity of blood varies in given cases. The authors suggest that the proper dose for a patient in a weakened state is from 1,000 to 1,500 cc. All their patients reacted with a brief chill, which as a rule occurred from one to two hours after the beginning of the transfusion when about 200 cc. of blood had been introduced. This was followed by a rise of temperature to 39 or 40 C. (102.2 to 104 F.). The temperature returned to normal the following day and the patients had a sense of well being. The authors emphasize the absence of grave symptoms even in the very weak patients in spite of the protracted reaction and ascribe it to the slow introduction of the blood.

**Treatment of Fibrous Encapsulating Peritonitis.**—Blumental was able to collect from the literature sixty-three cases of chronic encapsulating peritonitis in addition to three that he observed. The etiology of this rare condition has not been elucidated. It appeared in some cases to be of a tuberculous nature. However, it was not established that the existing tuberculous lesion was not secondary to the underlying pathologic process. The following factors were considered by various authors in its pathogenesis: diplococcus infection, rheumatism, typhus, malaria, chronic constipation leading to coprostasis and alterations in the serosa, acute enteritis with lymphatic extension to the serous surfaces of the intestine, and anomalous reaction of a constitutional nature to various infectious accidents within the abdominal cavity. The author leans to the view that polyserositis is a local manifestation of a general disease of unknown nature. He believes that a preoperative diagnosis is possible and should be based on manifestations of chronic partial intestinal obstruction with periodic exacerbations, characterized by only moderate distention of the abdomen and absence of a stormy peristalsis and the presence of a swelling and of loud intestinal sounds. The operative treatment consists in decapsulation and freeing of adherent intestinal coils. The postoperative period is characterized by manifestations of shock and intestinal paresis and should be combated by subcutaneous and rectal infusions, blood transfusions and administration of cardiac stimulants. Decapsulation leads to permanent cure in the majority of the cases.

Treatment and Prognosis of Empyema in Childhood. O. Utter.—p. 545.

**Routine Spinal Anesthesia.**—Nygaard reports 1,198 cases in which operation was performed under spinal anesthesia during the years 1928, 1929, 1930 and 1931 in the Gundersen Clinic (La Crosse, Wis.). A solution made from crystalline procaine was injected in a concentration of from 3.4 to 6.9 per cent at the rate of 1 cc. in from eight to ten seconds. By this technic the level cephalad to which the spinal anesthesia extends is controllable by gravity. This is in contrast to the technic described by Labat, which is based on dilution and diffusion of the anesthetic agent. Spinal anesthesia was successful in 94.8 per cent of 1,198 cases. Nausea and vomiting were

observed in 33.5 per cent of 1,172 operations performed under spinal anesthesia. Symptoms referable to the cardiovascular system were recorded in 11.5 per cent and symptoms referable to the respiratory system were encountered in 2.9 per cent. A definite state of shock during anesthesia occurred in 0.83 per cent of the cases, with complete recovery of all except one patient, who died on the table. The incidence of the complications mentioned was higher in association with upper abdominal operations than with lower abdominal and extra-abdominal procedures. The mechanism of shock during spinal anesthesia may be due to the spinal anesthesia itself or to factors of extrinsic nature, such as incorrect posture of the patient, the use of the gallbladder bar or kidney bar, breaking open the operating table, the extreme Trendelenburg position, or the prolonged exposure of the operative field. Close cooperation is urged between the anesthetist and the surgical team when the patient appears to be in a condition of impending shock. Postoperative complications such as nausea, vomiting, headache, backache, urinary retention, pulmonary complications and nervous sequels in 1,172 cases of spinal anesthesia were compared with the postoperative complications that followed similar types of operations performed under ether anesthesia in 602 cases. Nausea occurred in 7.9 per cent of the cases in which spinal anesthesia was used and in 7 per cent of cases in which ether was used. Backache occurred in 6.9 per cent of the cases in which spinal anesthesia was used and in 7.8 per cent in which ether was used. Urinary retention occurred in 9.3 per cent of the cases in which spinal anesthesia was used and in 12.1 per cent in which ether was used. Pulmonary complications occurred in 2.3 per cent of the cases in which spinal anesthesia was used and in 4.7 per cent in which ether was used. The use of ether anesthesia was followed by a much higher incidence of postoperative vomiting (51.8 per cent) as compared to spinal anesthesia (36.3 per cent). Postoperative headache was more frequent and more severe following spinal anesthesia (22.4 per cent) than that of ether anesthesia (13 per cent). A much higher incidence of postoperative complication was noted among women than among men; this holds true for spinal as well as for ether anesthesia. The nervous sequels following spinal anesthesia were neuritis in both lower extremities, combined left-sided paralysis of the abducens nerve and partial paralysis of the right facial nerve, complete paralysis of the right facial nerve and progressive myelitis. A comparison of the total postoperative complications that were observed in each group of cases in this series would indicate that there are fewer complications following spinal anesthesia than following general anesthesia.

**Protamine Insulin.**—Schnohr states that, in patients suffering from diabetes complicated with abscesses, arteriosclerotic gangrene, moist gangrene and complications following operations on the kidneys, the effect of protamine insulin was smoother and more protracted than that of ordinary insulin, the effect of protamine insulin as a rule being about twice as long as that of ordinary insulin. By administration of ordinary insulin in the morning and interchanging ordinary insulin with protamine insulin in the evening an actual depression of high values of the fasting blood sugar was obtained and the larger fluctuations in the blood sugar throughout the day were avoided. During treatment with protamine insulin the hypoglycemic attacks disappeared or became fewer, the excretion of sugar decreased and the tendency toward acidosis was well controlled. It has been shown that protamine insulin is effective despite liberal intake of carbohydrate. Administration of protamine insulin was accompanied by a feeling of physical fitness and a sense of well being. Local reactions, protein reactions or failure of the insulin effect have not been observed. A patient having medullary symptoms either of diabetic origin or because of hypersensitiveness to ordinary insulin was relieved of symptoms when protamine insulin was substituted for half the ordinary insulin. Along with the improvement in the diabetic state as demonstrated by exact methods, the surgical disease seemed to take a beneficial course when treated with protamine insulin. The author concludes that protamine insulin should be used in surgical complications of diabetes when any significant fluctuations of the blood sugar are present.

**Ether Convulsions.**—Payne discusses ether convulsions from the study of five cases of generalized convulsions occurring during ether anesthesia. Ether convulsions appear to be a definite clinical entity. Convulsions are confined to anesthesia in which ether has played a part and are quite distinct from jactitation during cyanosis in prolonged nitrous oxide anesthesia. They are also to be distinguished from "ether clonus," as ether clonus develops early in anesthesia before full surgical anesthesia has been attained. Ether convulsions are rare, and, when fatal, death occurs without recovery of consciousness either on the operating table or as long as two or more hours after the onset of convulsions. They are not dependent on the position of the patient, are not confined to the limbs, and usually occur after anesthesia has been in progress for half an hour or more. Anesthesia is often deep, and the administration of more ether or chloroform is contraindicated. On the basis of an analysis of the five cases reported and of those recorded in the literature, it may be said that ether convulsions are due to a combination of several factors. The most important of these are the youth of the patient, the presence of acute toxemia or sepsis, deep ether anesthesia, the use of methods in which the ether is heated, and high external temperature. No one factor is sufficient by itself to cause convulsions. In the treatment of the established convulsions the anesthetic should be stopped at once and a clear airway obtained, the head raised, a 7 per cent carbon dioxide mixture in oxygen administered, and the apnea treated by insufflation of the lungs, artificial respiration and the introduction of an endotracheal catheter. In prolonged or recurrent cases N-methyl-cyclohexenylmethylmalonyl-urea sodium should be injected intravenously, a dose of from 3 to 8 cc. being usually sufficient. In these cases large doses of potassium bromide and chloral hydroxide should be given rectally.

**Vitamin C Deficiency in Addison's Disease.**—Wilkinson and Ashford discovered a vitamin C deficiency in three cases of Addison's disease by the urine titration method of Harris and Ray. There was a subnormal concentration of cevitamic acid in the urine and very low twenty-four hour excretion during the control period. This was followed by responses, of varying slowness, to the repeated oral administration of large test doses of the synthetic l-cevitamic acid. When therapy was discontinued, the increased excretion fell rapidly to values characteristic of the control period. The degree of subnutrition paralleled the severity of the disease in the three cases investigated. Therefore subnutrition may be a feature of the disease or it may simply be an entirely nonspecific index of the extremely low state of health of the patient. There may be an increased need for the vitamin or an increased destruction of it. Such increased destruction has been shown in different febrile conditions by a number of observers. Pyrexia, however, is not a feature of Addison's disease except

in the terminal few days of the tuberculous cases. It is not possible to relate the vitamin deficiency in the three cases to lack of storage in the damaged adrenals. The significance of the normally very high cevitamic acid content in the adrenals may be that it is concerned with the maintenance of a correct state of oxidation-reduction potential in the adrenals and would thus serve to stabilize both the medullary hormone and the cortical hormone, or that it is concerned in the regulation of skin pigmentation. The pigmentation of the cases reported did not show any appreciable change during the test period of intensive oral cevitamic acid therapy. It is possible that defective absorption may have contributed to this negative effect, but it was not considered desirable to give any further intramuscular treatment at this time. The patients were steadily getting better during the time of the tests, as a result of vigorous intramuscular injections of adrenal cortex extract. Since discharge from the infirmary, two patients have received a high vitamin C diet and intramuscularly small (2.5 cc.) doses of adrenal cortex extract at irregular intervals of several weeks. During the last three months the pigmentation has decreased. Whether this improvement is to be related in any way to the high vitamin C diet (the urinary vitamin C excretion has now reached "normal" levels) or to the gradual remission of the disease under the adrenal cortex extract is impossible to say, making further observations necessary.

**Acid Values in Purulent Discharges.**—Waugh made 314 examinations of pus from 175 cases, of which seventy-eight were taken from cases treated by the Winnett Orr method, and the  $p_H$  value was obtained in forty specimens. The investigation indicates that pus in a wound is normally alkaline in reaction. Pus in a wound treated by the Winnett Orr method undergoes a change to acidity. This acidity is a prime factor in hastening the separation of sequestrums and inhibiting the ectopic deposit of calcium and formation of involucrums. It is justifiable therefore to employ in the pack lotions of a definite acid character; procaine hydrochloride, being a hydrochloride, possessing a  $p_H$  value less than 7, is a suitable agent, having in addition a desirable analgesic effect. It is possible that the acidity acts as a stimulus to formation of primary mesoblastic tissue and the growth of granulations, and accelerated wound healing. There can be little doubt that the spread of immobilization methods in prevention and treatment of wound infections constitutes a considerable advance in the technic of treatment. Reports on these, however, have been predominantly clinical in character; further chemical and bacteriologic research is desirable in view of the widespread adoption of Winnett Orr methods.

which later returns to normal ciliated columnar (if there is not a chronic inflammatory process present); fibrosis of tunica propria; dehydration of edematous tissue; fibrosis of blood vessels, and in some cases cartilaginous necrosis.

Boling,<sup>7</sup> working in the department of cytology at Washington University School of Medicine, showed that following ionization of the sheep's nose there was a complete regeneration of the ciliated epithelium. Wenner has made the same observation on cats. In the human subject, probably because of the fact that we were dealing with chronic inflammation of the mucous membrane in the beginning, we have always found areas of persistent squamous cells following the ionization. Biopsies were made from the same area on the inferior turbinate before and after ionization. Before ionization the cells were all ciliated. One month after ionization no ciliated epithelium was present, the epithelium being all stratified squamous. Three months after ionization the only ciliated epithelium found is in a small depression in the mucous membrane, which may have caused the epithelium at that point to be unaffected by ionization. It is true that the more insult there is to the nasal mucous membrane the more stratified epithelium will be found. Theoretically it is to be expected that, following the necrosis of the superficial tissue that occurs with ionization, there will be more squamous epithelium than before.

During the last year we have been interested in the activity of the cilia of the cells that were regenerated following ionization. One patient had particularly good cilia in the microscopic section of a biopsy after ionization. Some of these cells were removed and studied by Miss Pfingsten. She compared their activity with the activity of the cilia of normal cells and also the length of time that the cilia beat when kept in nutrient solution in the culture chamber following removal. The activity and the length of time that they beat were practically the same in the normal and in the regenerated ciliated cells. This patient had been ionized some eight or ten months before because of a chronic vasomotor rhinitis. The mucous membrane of this patient was much drier than normal. Several members of the staff looked at this patient's nose and all agreed that, while the cilia might be beating in the lower layer of mucus, the mucus covering the membrane was so dry that it was impossible for the cilia to produce any movement on the surface.

We have convinced ourselves<sup>8</sup> that some form of mucosal test is necessary in studying allergic rhinitis. The comparison of the results of intramucosal tests with skin tests shows that often the skin will give a negative reaction for an allergen to which the mucous membrane of the nose is sensitive.<sup>9</sup> It has been found that, by avoiding the allergens to which the mucous membrane is sensitive and to which the skin did not react, a satisfactory result has been secured.

During the last year Wenner and Alexander<sup>10</sup> have made a study of the action of ionization and of the galvanic current on the vasomotor mechanism of the nose. They proved that the blood vessels of the nasal mucous membrane failed to react to vasoconstrictors and vasodilators for six weeks after zinc ionization in

the cat's nose and for four weeks after treatment with the galvanic current. They were unable to determine whether this was due to a paralysis of the vasomotor nerves or to a loss of vascular tone. The absorption of drugs by the mucosa was not affected by ionization.

During the last year we have also been interested in the influence of ionization in the nasal mucous membrane on the absorption of allergens by the membrane. Three patients who were ionized because of chronic vasomotor rhinitis were studied before and after ionization in order to determine the relative absorption of allergens through the untreated and treated mucous membrane. The method described by Sulzberger and Vaughan<sup>11</sup> of determining the absorption of allergens through the mucous membrane of the nose was used. These three patients were nonallergic to ragweed. Blood containing reagins to ragweed was injected into the skin of one arm. This produced a local sensitivity to ragweed pollen. A similar amount of blood without the reagins to ragweed was injected into the other arm. The first patient tested had had one side of the nose ionized sixteen days before. Twenty-four hours after the arm was injected, the ragweed pollen was placed in the un-ionized side of the nose. In fifteen minutes there was a reaction apparent on the arm at the site of the injection of the blood containing the ragweed reagent. The other arm did not react. This was repeated on the ionized side of the nose. There was no reaction on either arm in twenty-four hours. The other two patients had the same test made except that the test was made before and after ionization. In the first case before ionization the reaction in the arm started in ten minutes and reached a maximum in thirty-three minutes. Eight days following the ionization, the test was repeated with negative results. In the second case before ionization the reaction started in thirteen minutes after the injection and reached its maximum in one hour and thirty minutes. Twenty-one days after the ionization, the absorption test was again made. The reaction in the arm in this instance started in forty-three minutes and reached its maximum in one hour and forty-three minutes. The reaction following the ionization was more marked than that which preceded it.

We have had the opportunity of studying the influence of ionization on the absorption of allergens by the nasal mucosa in only three cases. It is interesting at least to note that in two cases there was no evidence of absorption at all of the ragweed pollen through the mucous membrane of the ionized nose, while in the third case the absorption was delayed.

Further studies during the last year on the human nose, taking biopsies before and after ionization, have suggested that the final results of ionization were fibrosis and thinning of the tunica propria; that the basement membrane is thicker and more dense; that there is a hyperplasia of the epithelium with increase in metaplasia; that very few goblet cells are present; that sometimes there is a thickening of the vessel walls, particularly the capillaries; that the number of eosinophils in the tissue is not decreased, and that the secretory glands are partially destroyed.

Some of the acini of glands appear to be completely obliterated by cellular hyperplasia. In others the secretory cells are atrophied. Marked inflammation may be present around the acini. These changes result in an

**Ventricular Asynchronism After Section of Branch of Bundle of His.**—Braun Menendez and Solari made experiments to ascertain the existence of ventricular asynchronism. The authors found that in normal dogs contraction of the two ventricles takes place synchronously (external cardiograms). The beginning of ventricular contraction is nonsynchronous. Aortic ejection may go 0.005 second before pulmonary ejection or the latter from 0.005 to 0.02 second before the former. The closure of the semilunar valves is, as a rule, nonsynchronous. The pulmonary semilunar valves may close 0.02 second before the aortic semilunar, or the latter from 0.02 to 0.03 second before the former. After section of the right branch of the bundle of His, the left ventricle contracts from 0.04 to 0.06 second before the right one. This fact can be observed by graphic determinations of intraventricular pressure and by external cardiograms. The period of aortic ejection begins within 0.015 and 0.055 second before pulmonary ejection. Closure of the aortic semilunar valves takes place in an average of 0.06 second before that of the pulmonary semilunar valves. There is reduplication and increased duration of the first heart sound. The authors' results show the rôle of the branches of the bundle of His in conducting stimuli from the auricles to the ventricles. Following section of the right branch, the ventricular contraction becomes asynchronous. The experimental asynchronism allows one to explain the clinical signs of bundle branch block.

**Biopsy.**—Between 1931 and 1935, Fehr states, 1,300 cases of malignant neoplasm were admitted to the surgical clinic of the University of Zurich. Biopsy was necessary and possible in 288. Of these, 248 proved to be malignant and forty benign. Diagnosis was not the sole indication for a biopsy. The roentgenologist who irradiated accessible neoplasms of the skin and mucous membranes depended entirely on the biopsy for the determination of the kind of tumor, its malignant or benign condition and its x-ray sensitivity. Biopsy is an indispensable first step in this method of therapy. Correct diagnosis by clinical methods alone was possible in 70.1 per cent of the material, while the biopsy method gave 87.8 per cent of correct diagnoses. The principal source of error in the biopsy method is the improper removal of the material to be examined. For this reason a negative histologic observation is not a sufficient proof that a malignant condition does not exist. The author mentions hemorrhage, infection and activation of the growth as the hazards of the biopsy method. They are rather infrequent and may be limited to an altogether negligible quantity by proper precautions. While the author is not aware of a single scientifically proved case of "wild dissemination" of cancer cells after a biopsy, he feels that the latter should never be performed in the case of melanocarcinoma because of its exceptional sensitiveness to trauma. He is likewise opposed to biopsy in mammary carcinoma except in doubtful cases. The author is an adherent of the frozen section method, which need not take more than ten minutes and is entirely reliable. Diagnosis of malignancy must be followed immediately by radical operation. Further prevention of infection and dissemination of cancer cells may be accomplished by the use of a diathermy knife and searing of the wound after the excision. It alters the histologic picture, however, and makes the finer differentiation of the morphology of the cells difficult. Malignant con-

ditions of the esophagus can be readily diagnosed with the aid of roentgenology and esophagoscopy, while biopsy is likely to produce bleeding or infection. Cystoscopy yields more information than biopsy. The latter secures only superficial layers, while a malignant degeneration is as a rule more deeply seated. Furthermore, it may produce hemorrhage or cystitis. The author calls attention to some of the difficulties in the histologic diagnosis. Thus differentiation between fibrous osteitis and osteogenic sarcoma or between osteomyelitis and Ewing sarcoma may be difficult or impossible. The excision here should be deep and preferably multiple; otherwise one will encounter only the tissue seat of a defense reaction produced by the growth and not the growth itself.

**Hepatorenal Syndrome.**—Pytel believes that certain phylogenetic, anatomic, physiologic and pathologic relationships of the liver and the kidneys point to an interdependence of the two organs. There is a definite clinical picture which may be properly designated as a hepatorenal syndrome. It may be observed in diseases of the liver and the bile passages, particularly in the postoperative period or following acute traumatic lesion of the liver. The syndrome caused by hepatic and renal insufficiency produces characteristic symptoms. The author succeeded in demonstrating in his animal experiments that damage to the liver is followed by suppression of the renal function with pathologic alterations in the glomeruli and in the convoluted tubules. His experiments point to a toxin originating in the areas of liver necrosis and circulating in the blood stream. He has performed four series of experiments in rabbits: (1) ligation of the hepatic artery, (2) subcapsular traumatization of the liver parenchyma, (3) intraperitoneal injection of liver extract and (4) intravenous injections into a normal rabbit of from 5 to 10 cc. of blood removed from a rabbit with an experimental hepatorenal syndrome. All the experimental animals developed varying degrees of oliguria, with albumin and erythrocytes in the urine, marked azotemia, loss of weight, apathy, and in some cases death. Necropsies demonstrated areas of necrosis in the liver, while the kidneys showed pronounced stasis in the blood vessels of the malpighian bodies, hemorrhages in the Bowman capsules, and cloudy swelling and degeneration of the epithelium of the convoluted tubules. The author assumes the existence of a toxic substance resulting from liver necrosis, circulating in the blood stream and exerting its influence particularly on the kidneys and to a lesser degree on other organs. The toxic substances originate in the areas of liver necrosis or are brought to the liver from the intestine and fail to be detoxified in the former as the result of loss of its functional capacity. The effect of these toxins is exerted on the blood vessels, in particular on those of the malpighian bodies, as well as on the epithelium of the convoluted tubules of the kidney.

**Indications for Surgical Treatment of Tuberculosis.**—According to Brunner, bilateral pneumothorax therapy has demonstrated the possibility of treating bilateral tuberculous disease of the lung by compression of the pulmonary tissue. The author stresses the advantages of leaving functioning pulmonary tissue undisturbed while attempting surgically to affect definitely diseased foci. He advises against phrenico-exeresis in cases in which artificial pneumothorax therapy has failed. The effect of the former in the treatment of old, stiff-walled apical cavities is negligible. The operation itself is not without its hazards. In a review of the literature, Berry reported 4,697 phrenico-exeresis operations with fifty-seven grave complications and twenty-six fatalities. The author points out that, in the presence of normal lower lobes, phrenico-exeresis on the left side can lead to unrestricted rise of the diaphragm and serious disturbances on the part of the stomach, the esophagus or the heart. On the basis of his operative material between

chronic vasomotor rhinitis, ionization may be used. Its best and most permanent result is secured in chronic nonallergic vasomotor rhinitis. We have observed a patient with chronic vasomotor rhinitis who had one side of his nose ionized. Three months before, the patient had had acute upsets of the upper respiratory tract which were nonallergic. The un-ionized side of the nose was pink, blocked and actively secreting. The ionized side of the nose was dry with good breathing space and the mucous membrane; instead of being pink and actively secreting, it was pale and only slightly moist.

#### STUDY OF THE PATIENT

A second essential in the treatment of allergic rhinitis is a most careful study of the patient. With our patients we are definitely of the opinion that, if after careful study we are not getting a good result from treatment, we have overlooked something and the patient must be studied again. It is a common thing in the management of the treatment of perennial cases of allergy for us to go back and restudy the case.

The history is a most important part of the study, and still one must be sure not to be too much influenced by it. The finding of a gastro-intestinal allergy does not make a diagnosis of an allergic rhinitis in the patient if he has an upset of the upper respiratory tract. A patient may have a gastro-intestinal allergy and still have a chronic vasomotor rhinitis which is not necessarily allergic.

Nasal smears and a blood count should be made in every case. It is certain that in trichinosis and other parasitic diseases and in digitalis and other forms of poisoning one may have a great increase in the eosinophils in the nasal discharge without having an allergic rhinitis. At the same time there will be an increase in the eosinophils of the blood. Up to this time we have never seen a patient with an edematous nose and a marked increase in the eosinophils in the nasal discharge who did not prove to be allergic. An exception to this may be found at any time. An x-ray examination of the sinuses should be made, because a thickened sinus lining is always suggestive of an allergic condition.

A bacteriologic examination is most important whether there is definite infection of the nasal sinuses or not. There is such a thing as bacterial allergy. Biopsies of the tissue present the same picture of edema with a great increase in eosinophils, as is found in other forms of allergic rhinitis. If there is any suspicion of bacterial allergy and organisms have been cultured that are suitable for making a vaccine, the tests must await the preparation of a vaccine. Skin reactions and systemic reactions follow the use of vaccine in cases of bacterial allergy. We are inclined to think that the greater the reaction the better the prognosis from the use of a vaccine.

Dietary deficiencies must be sought. One should not put the patient on a diet that is made deficient by excluding certain substances to which the patient is sensitive. It is inexcusable to take from the food supply a given essential food without replacing it with something equally good. This is sometimes a definite problem.

We have proved conclusively in our clinic that we do not get as good results from the administration of vaccines or from the desensitization of patients with allergic rhinitis if the patient is not on a proper diet. Ragweed hay fever patients are sensitive to other sub-

stances, particularly foods. Not only are these patients improved by the avoidance of foods and other allergens to which they are sensitive, but a good diet helps with the hay fever.

Trauma of the nasal mucous membrane of the nose and malnutrition both do something to the protective lining of the nose that permits allergens to enter into the tissue. This is the reason there are so many cases of asthma following operations on the tonsils. It is interesting to note that some of these patients have asthma only when they return to the community where the tonsils were removed. The break in the protective epithelium permits the entrance of allergens into the tissue, and sensitization results.

Endocrine disturbances should be sought and, if present, corrected. We have a basal rate determination made in every case of allergic rhinitis. We make skin tests in every case. We realize that they are often more an indication of the past allergic history of the patient than of the present. Reagins are formed in all tissues of the body except the cerebrospinal fluid and the aqueous humor of the eye. As soon as the acute allergic attack is over the organism starts excreting the reagins. They disappear from the blood and other circulating mediums of the body first. The skin is one of the structures from which they disappear last. A child may have been sensitive to milk at the age of 2 years and the sensitivity may have disappeared before the child reaches  $2\frac{1}{2}$  years of age and still give a positive skin reaction to milk at the age of 15 years. We would be unwilling to treat cases of allergic rhinitis without some test of the sensitivity of the mucous membrane of the nose to the various suspected substances. We like the intramucosal test. We have done more than a thousand tests without any deleterious results. It is axiomatic that we have not used serums and other similar substances that are very likely to cause severe systemic reactions. There is little or no danger with the various pollens and foods in the proper dilutions. Certainly it is a common occurrence to find the mucous membrane of the nose sensitive to a substance to which the skin does not react.

Passive transfers are not done as a routine procedure. We do them whenever we wish to know just how sensitive a given patient is to a certain allergen. Before we make a passive transfer, careful serologic tests are made. The serum of the patient to be tested is injected into the skin of a nonallergic person. If reagins to ragweed are in the serum used they produce local sensitization at the site injected. At the end of three hours the site of the injection is tested with ragweed pollen and the amount of reaction determines the amount of reagin or antibodies to those allergens in the serum.

The leukopenic index as worked out by Gay has proved to be of the greatest value to us in studying food allergy. The technician doing this work must be capable of making exact blood counts. It takes much of her time. In a number of cases, after a thorough study, if the treatment is not satisfactory and we do not get a good result the leukopenic index to determine food sensitivity is used. The results secured by this procedure, particularly when clinical symptoms are produced, are exact guides for therapeutic purposes. We are aided in the study of our cases by the results that are secured by the withholding of certain allergens or by the symptoms that are produced by their administration.

gens. He gives three sessions each week, until a total of about fifteen has been reached. After an interval of three weeks, the series may be repeated.

**Irradiation of Keloid Tumors.**—Hintze employed irradiation in the treatment of twenty-six patients with keloids. In seven cases roentgen and radium rays were employed; fifteen patients received only roentgen irradiations and four were treated only with radium. The roentgen irradiations were usually distributed over several weeks or months. The filtration consisted as a rule of 1 mm. of aluminum. The individual doses were chosen so as to avoid severe reactions. The radium irradiations were given either in the form of contact irradiations or from short distances. The slight wall thickness of the platinum-iridium needles served as filtration, but 1 mm. of brass or 1 mm. of lead was occasionally added to this. As in the case of the roentgen treatment, the radium irradiations were distributed over several weeks or months. In case of extensive keloids, a certain retrogression was at first effected by means of roentgen irradiations and the remnant was then treated with radium. The result of the irradiation was satisfactory in all cases, and in the majority of cases it was exceptionally good. In order to determine whether roentgen or radium irradiation is better for the treatment of keloids, the author applied radium rays to one buttock and roentgen rays to the other buttock in a patient who had keloids resulting from burns on both buttocks. It was found that exclusive roentgen treatment as well as exclusive radium treatment successfully counteracts large keloids.

**Meinicke's Tuberculosis Reaction and the Sedimentation Reaction.**—Hardt reports investigations on eighty-seven patients with pulmonary tuberculosis. The Meinicke reaction was positive in eighty-four cases. The three negative serums were from one patient with inactive tuberculosis, one with doubtful tuberculosis and one with a severe toxic form of pulmonary tuberculosis. The blood picture and the sedimentation speed of the erythrocytes were determined at intervals of three weeks. The author shows that a comparison of the Meinicke tuberculosis reaction with the blood picture and the sedimentation speed helps in the prognostic evaluation of active tuberculosis. Strongly positive Meinicke reactions and high numbers of lymphocytes indicate a favorable prognosis. The author's investigations revealed a parallelism between the blood picture and the Meinicke reaction, but he found that the sedimentation speed of the erythrocytes did not go parallel with these two factors and he thinks that the prognostic value of the sedimentation speed should not be overestimated.

**Hemorrhagic Pleural Exudates in Artificial Pneumothorax.**—Papanikolaou points out that, although pleural exudates are the most frequent complication of artificial pneumothorax, the hemorrhagic exudates are comparatively rare. He describes three such cases that came under his observation in the course of the last twelve years. All these patients had a predisposition to hemoptysis previous to the induction of the artificial pneumothorax and it is probable that this hemorrhagic tendency favored the later development of the hemorrhagic pleuritic exudate. The author thinks that a tuberculous hemorrhagic pleurisy or an intrapleural vascular rupture are responsible for the development of the hemorrhagic pleuritic exudate in cases of artificial pneumothorax. From observations on his own patients and from reports in the literature he concludes that the prognosis of the hemorrhagic exudates in artificial pneumothorax is usually a favorable one, for there is usually a spontaneous resorption of the exudate. The treatment may at first be conservative. The patient should remain in bed. Puncture becomes necessary only if the dyspnea and pains become severe. However, in cases in which the hemorrhagic exudate recurs again and again, extrapleural thoracoplasty should be done. The author ascribes the favorable outcome of one of his cases to an early extrapleural thoracoplasty.

Treatment of Articular Tuberculosis. F. Starlinger.—p. 1466.

**Total Thyroidectomy in Cardiac Disorders.**—Favorable reports of American authors about total thyroidectomy in angina pectoris induced Mandl to investigate this method. He employed the operation in seventeen cases. Four of the patients had hyperthyroidism with a predominance of cardiac symptoms, eight had chronic cardiac defects that could not be influenced by internal methods, two patients had angina pectoris with hypertension, one had obliterating endarteritis, one had dyspnea with severe emphysema and one had cardiac asthma and rectal carcinoma. Total thyroidectomy was done in all these cases and in spite of the poor general condition of the patients there was no operative fatality. All operations were done under local anesthesia (without epinephrine). The author discusses certain aspects of the surgical technic, particularly the management of the parathyroids. He corroborates the good results of other authors. The efficacy of the intervention is especially striking in patients with severe cardiac decompensation. He observed that cyanosis, pulmonary stasis, coughing and anxiety disappear within a few weeks. Regarding angina pectoris, he says that total thyroidectomy has competition from other operative methods, from the paravertebral injection of alcohol and from the surgical interventions on the sympathetic and the parasympathetic, so that the operative method which promises the best results is chosen for each individual case. The same applies to the cases of obliterating endarteritis, in which Leriche's operation is done with good success, but the author found that total thyroidectomy produced better results. In discussing the indications for total thyroidectomy, he warns against a too extensive application of this method. He does not consider it justified, as do some, in gastric ulcers, diabetes and severe infections.

**Etiology of Striated Meadow Dermatitis.**—Oppenheim reviews his own earlier studies and those of others on the etiology of striated meadow dermatitis and then describes his more recent studies on this problem. He demonstrates that striated meadow dermatitis is caused by a hypersensitivity of the skin to the volatile oils present in plants in meadows along river banks. Pressure and the prevention of the evaporation of the volatile oils doubtless are contributing factors in the development of this dermatitis, for in the numerous cases which the author observed in the course of the last ten years the dermatitis was always most severe on the sites that had been exposed to pressure: the back and the buttocks when the bather had lain in the dorsal position, the extensor surfaces of the arms and thighs, after lying on the side and the anterior side of the chest, and the abdomen and thighs after being in the prone position.

## DIATHERMY

A study also was made of the microscopic changes brought about by the use of the submucous diathermy. The subject of this study was a woman, aged 27, suffering from sneezing and rhinorrhea on an allergic basis. Relief was not obtained by the withdrawal of allergens.

Before diathermy, biopsies of the inferior turbinates showed a mucosa covered with pseudostratified ciliated columnar epithelium with many goblet cells. There were many areas of edema in the tunica propria, especially in the more superficial layers. A dense infiltration of lymphocytes, plasma cells and eosinophils was present. The glands were increased in number.

One month after diathermy, biopsy of the inferior turbinate showed the epithelium to be unchanged. The basement membrane was thicker but less dense than formerly. The inflammatory infiltration was unchanged. In the tunica propria was a dense band of fibrous tissue. Its fibers radiated inward to the fibrous layer of the periosteum and out to the epithelial layer. The epithelium was drawn in, forming a deep fissure on the surface of the turbinate as though by contraction of the scar tissue. The glands in this region were distorted by the scarring.

At the time of biopsy, one month after diathermy, diathermy was repeated on the left side because some edema persisted. A week later another biopsy was taken. The same changes were observed; that is, scarring and loss of edema. In addition there was a metaplasia of the glandular epithelium and the epithelium of the ducts, whole groups of acini being lined by stratified epithelium.

## TRICHLOROACETIC ACID

In London in 1897 it was said that 50 per cent trichloroacetic acid was good to use in rose colds because it paralyzed the end organs of the vasomotor nerves. Norval Pierce used it after the removal of edematous polyps to prevent their return.

A case of chronic vasomotor rhinitis associated with perennial allergy was selected for the study of the action of this drug. Cotton on a probe dipped into 50 per cent trichloroacetic acid was used to make a streak on the medial surface of the turbinate extending from the posterior to the anterior end. At the end of a week the nasal stoppage had disappeared and the patient had a good clinical result, at least for the time being.

Antedating the application of the trichloroacetic acid, a biopsy was taken from the right middle turbinate. Thirteen days following the application of the 50 per cent trichloroacetic acid, a biopsy was taken from the right inferior turbinate. The first biopsy was taken from the middle turbinate and the second from the inferior turbinate in order to obviate changes in the second biopsy due to trauma. The piece removed before the application of the acid showed the following: The epithelium was ciliated and columnar and numerous goblet cells were present; the basement membrane was pale and thickened; the tunica propria was edematous and infiltrated with a large number of eosinophils together with a few plasma cells and lymphocytes; the glands were active; the blood vessel walls appeared normal.

The biopsy taken thirteen days following the application of trichloroacetic acid showed the following: On the margin of the inferior turbinate there was a deep ulceration, the base of which was necrotic. The

necrotic tissue and the viable tissue around it were densely infiltrated with chronic inflammatory cells. The epithelium at the edges of the ulceration was stratified and squamous, while that farther away from the ulcer was ciliated. There was a hyperplasia of the fibrous tissue in the region of the base of the ulcer.

## THE ACTUAL CAUTERY

To study the action of the actual cautery, a biopsy was taken of a patient who had been cauterized four months before because of nonallergic vasomotor rhinitis. The patient secured only partial relief from the cautery. To study the immediate action of the cautery, puncture was made of edematous tissue on the middle turbinate of a patient suffering from chronic vasomotor rhinitis, and in another patient an edematous polyp was punctured with the cautery tip. The biopsy through the right inferior turbinate which had been cauterized four months before showed that the epithelium was ciliated. In it there was a depression, at the base of which was an area of dense fibrous tissue. Glands in this region were distorted by scarring but were active. There was no edema in the tunica propria in the region of the scar, although at some distance from it edema was seen.

The edematous tissue on the middle turbinate seven days after the application of the cautery showed that the area not cauterized was covered with ciliated columnar epithelium; the tunica propria was moderately edematous with some infiltration with plasma cells, lymphocytes and eosinophils. At the site of the cautery puncture there was a coagulation necrosis; the surrounding tunica propria was fibrous; there was a metaplasia of cells in the acini of the secretory glands; the blood vessel walls were thickened; around the site of the puncture was an infiltration of a large number of polymorphonuclear neutrophils and a few lymphocytes.

When the edematous polyp was punctured, a large amount of clear fluid escaped from the puncture. Three days after the cautery, grossly, a thick white membrane covered the polyp; the membrane was adherent to the underlying tissue. Microscopically this membrane was a thick exudate covering the area where the epithelium had been destroyed. The surface of the polyp not cauterized was lined by ciliated columnar epithelium. Beneath the exudate there was a marked infiltration of polymorphonuclear neutrophils and there were a few lymphocytes. The lesion produced was one of coagulation necrosis with fibroblastic proliferation in the polyp.

## ALCOHOL

Cats were used for the study of the action of alcohol on the mucous membrane of the nose. The cats were anesthetized by the intraperitoneal injection of 2 or 3 cc. of a 10 per cent solution of sodium amytal. After the nasopharynx was packed off with petrolatum gauze, one nostril was filled with 70 per cent alcohol, which was left in for twenty minutes. Dr. Robert E. Parrish<sup>22</sup> suggested that if alcohol packs were used in the nose for allergic rhinitis they should remain in the nose twenty minutes.

In each case there were sneezing and struggling movements. In about ten minutes a bloody discharge was noted. Cats were killed at various intervals and the nostrils were sectioned and stained for histologic study.

In cats killed two days after treatment, the treated nostril was occluded by a red edematous mucous mem-

## THE TREATMENT OF ALLERGIC RHINITIS

WITH PARTICULAR REFERENCE TO IONIZATION AND  
THE CONTROL OF CHRONIC VASO-  
MOTOR RHINITIS

L. W. DEAN, M.D.; LLOYD D. LINTON, B.S.;  
H. M. SMIT, M.D.; L. W. DEAN JR., M.D.  
AND  
CHARLES MAHONEY, M.D.  
ST. LOUIS

Twenty months ago the Department of Otolaryngology in the Medical School of Washington University decided to make a study of allergic rhinitis. The late Frank E. Ball of Muncie, Ind., created the Frank E. Ball Research Fund to carry out this study.

Antedating this research, two observations regarding ionization had already been made in the department. McMahon<sup>1</sup> reported that ionization in dogs produced a fibrosis of the subepithelial tissue with marked hyperplastic bone changes; that the epithelial changes in the nose consisted of a primary destruction of cells with a later return to normal. The Alexanders<sup>2</sup> reported that it was the patient who suffered from hay fever and had no reagins in the blood stream who was more likely to get a good result from ionization, while the one who had an abundance of reagins in the blood stream as a rule had an unsatisfactory result following the treatment. Hansel<sup>3</sup> made an excellent and comprehensive review of allergic rhinitis.

A group of scientists, some doctors of medicine and some not, were engaged to further this investigation. This is a report of part of the work done. The immunologic work reported was done by L. D. Linton; the pathologic work was done by and the study of the action of radium and of surgical diathermy on the mucous membrane was made by L. W. Dean Jr.; the study of the action of alcohol and of phenol (carbolic acid) in the nasal mucous membranes of animals was made by Charles Mahoney, the study of the action of trichloroacetic acid and the actual cautery on the nasal mucous membranes by H. M. Smit. Wenner<sup>4</sup> has shown that ionization of the frog's foot slowed the circulation in

from eight to fifteen minutes; that a clumping of the red blood cells took place in forty-five minutes; that the circulation was completely stopped in one hour; that if the electric current alone was used the circulation was not stopped and the clumping of blood cells did not take place. Similar observations were made on a rabbit's ear. Wenner studied the influence of zinc iontophoresis on the feet of guinea-pigs and concluded that the resulting ulceration of the skin and gangrene of the feet was probably in part, at least, caused by the circulatory disturbances and made the observation that small electrodes if used in ionization were more likely to cause ulceration than the larger ones.

### RESULTS OF IONIZATION

Later Wenner<sup>4</sup> demonstrated that so-called ionization was in reality iontophoresis; that the zinc ions actually penetrated the skin and cartilage of the rabbit's ears during the process of ionization.

Linton<sup>5</sup> made intramucosal tests before and after iontophoresis. If the patient gave a positive intramucosal reaction before ionization he always gave a positive reaction after the treatment. Some patients who received relief from allergic rhinitis from the use of iontophoresis did not react to the topical application of allergens to the mucosa, but they always reacted to the intramucosal injection of the ragweed pollen if they were ragweed hay fever cases. He secured a reaction in one case as early as eleven days after iontophoresis. He has since noted that trauma and other procedures in the nose influence the reaction of the mucous membrane to allergens; that is, for instance, the removal of polyps, submucous resection and the like may interfere with the reactions when intramucosal tests are made. He has also noted that local desensitization of the mucous membrane may result from the injection of an allergen. For example, in a case of hay fever in which ionization has been done an intramucosal injection of ragweed pollen was given to test the sensitivity of the mucous membrane. This resulted in a terrific attack of hay fever, which could be controlled only by an injection of epinephrine. A repetition of this injection ten days later produced no reaction. It has been noted many times that intramucosal tests in allergic rhinitis may themselves produce a clinical improvement.

Smit<sup>6</sup> studied the tissue changes following zinc iontophoresis. His observations are as follows:

Summarizing the tissue changes which one finds following zinc iontophoresis, there occur: coagulative necrosis of the epithelium; early stages of inflammation with polymorphonuclear leukocytes which are later replaced by round cells; atrophy of glands and loss of glands; metaplastic changes in glands and ducts; formation of stratified squamous epithelium

This investigation was made possible by the Frank E. Ball Research Fund.

These observations bring us to the conclusion that if a successful result can be secured in chronic vasomotor rhinitis by treatment on an allergic, dietary or endocrine basis, or by the correction of septal deformities, or by the removal of adenoids or the eradication of infection, the desired result will be secured without deleterious changes in the mucous membrane of the nose. When one resorts to ionization or to the use of phenol, trichloroacetic acid, alcohol, the cautery or any of the methods mentioned in the latter part of this paper, one produces deleterious changes in the nasal mucosa.

## THE VISCERAL NERVOUS SYSTEM AND ITS RELATION TO THE ENDOCRINES

HOMER P. RUSH, M.D.

PORTLAND, ORE.

Many vegetative functions of the human organism have been shown to be under the influence of the visceral nervous system.<sup>1</sup> It has also been shown that many vegetative functions are under the influence of the endocrine system. At least some of these vegetative functions have been observed to be affected by both systems. These facts have led to various conclusions. By some investigators the visceral nervous system has been given the dominant rôle, while other investigators have relegated the visceral nervous system to a minor rôle, placing the primary importance on the endocrines. On the other hand, statements are not uncommonly found in the literature that suggest a duality of control between these two systems. Zondek<sup>2</sup> says "It should be emphasized that the hormonal system does not, as was supposed by many writers, fulfil the rôle of sole governor of vital functions but that in this respect it is an equivalent link with the nervous system." Jelliffe<sup>3</sup> concludes that "From the evolutionary attitude the vegetative nervous system looks after the chemisms of the human body, hence its function is related to the earliest part of the past in the unconscious denominator. The phylogenetically oldest part of the vegetative nervous system and that part which still maintains the loosest of structural relationships is the endocrinous gland system." I feel that vegetative regulation is the result of a most complicated interdependence between these two systems and offer the following examples to substantiate this point of view:

1. The visceral nervous system does produce an effect on certain endocrine glands. This opinion seems justified in the case of the posterior lobe of the pituitary when the following work of Ranson<sup>4</sup> is reviewed: He and his co-workers have shown that permanent

polyuria (diabetes insipidus) could be produced by specific lesions, bilaterally, involving the supra-optic nucleus, the tractus supra-opticohypophyseus, or the posterior or intermedial lobe of the hypophysis. It is usually reasoned that these lesions prevent the anti-diuretic principle which is a specific hormone coming from the posterior or intermediate lobe from acting directly on the kidneys to prevent excessive excretion of urine, which diuretic action they show from the diuretic factor produced by the anterior lobe. It is further interesting to note that Ranson<sup>5</sup> has been able to control the polyuria of the nerve lesion by injecting an endocrine product; namely, solution of posterior pituitary. Here, then, is an example of a visceral nervous lesion apparently producing symptoms because of a lack of the hormone being excreted in an endocrine gland, and these symptoms can be relieved when this hormone is readministered to the organism.

Dandy<sup>6</sup> has shown that sympathetic fibers from the carotid plexus accompany vessels down the stalk of the pituitary to the anterior lobe. Kary<sup>7</sup> and Lewy<sup>8</sup> have observed retrograde cell changes in the supra-optic and tuber nuclei of the hypothalamus after injury to the posterior lobe of the pituitary in the dog. Davis,<sup>9</sup> working in Ranson's laboratories, made the following observations: Stimulation of the superior cervical ganglions produces glycosuria and hyperglycemia. If a hypothalamic lesion was previously produced, this effect was not obtained. Furthermore, it was not obtained after bilateral splanchnic section. When to these observations are added those of Houssay<sup>10</sup> in which he was able to control the hyperglycemia of depancreatized dogs by pituitary removal, one may conclude that the pituitary has a distinct effect over carbohydrate metabolism and that this effect may be influenced by the visceral nervous system.

One seems justified in assuming that certain clinical observations reenforce the aforementioned laboratory results. The classic example is the development of exophthalmic goiter following psychic trauma. The observations of de Takáts<sup>11</sup> and others that diabetes mellitus has been frequently influenced by denervation of the adrenals is suggestive of some nervous control over this gland.

2. There is some regulation of the endocrine function by higher centers. The experiments of Ranson would be suggestive of this conclusion. Beattie and his co-workers<sup>12</sup> have been able to show that stimulation of certain hypothalamic centers caused a widespread flow of impulses over the sympathetic system. This would lead to an increase in adrenal output.

3. In some instances, it appears as though a given tissue reaction needs both the visceral nervous system and the endocrine system. The foregoing work not only suggests the probability of central control over certain incretory activity but further suggests the

interference with the secretory function of the nasal membrane, and the membrane does not swell as easily as it did before. Biopsies taken from the human nose are necessarily superficial. Periosteal changes have been found in the occasional biopsy in which a piece of bone was secured. In human biopsies the cartilage of the septum could not be studied. In dogs and guinea-pigs, some cartilage cells were killed by the ionization.

We have proved to our satisfaction that ionization does not change the allergic status of the body in any way. While dusting allergens in the nose may not cause a reaction after ionization, the tissues of the nose always react as before ionization to the intramucosal injections of allergens. With intramucosal tests there is a difference; namely, the tissues do not swell as before. There is no change in the reagin content of the blood. It has been found however that, by using different individuals to test the reagin content of the blood and by using the same blood, different results may be secured. This may explain the suggestion that has been made that the allergic status of the individual is changed by the ionization.

We do not find it necessary to use ionization for the control of hay fever. It is used to control the chronic vasomotor rhinitis that persists after the hay fever season. It is interesting to note that we had on Sept. 1, 1936, in our research clinic five patients who were ionized one or two years ago for hay fever with unsatisfactory results. One of these patients is doing very well with desensitization, diet, hormones and the like. The other four are not doing well. The patients who are highly sensitive to ragweed pollen, those who have plus 4 reagins in the blood stream, are very difficult to handle with any kind of treatment except the avoidance of allergens. All other hay fever patients in the clinic are doing well with desensitization, diet, avoidance of other allergens to which they are sensitive, correction of endocrine dyscrasias, and other measures.

We have used ionization for the control of chronic vasomotor rhinitis when other forms of treatment have failed. It has been used when all the mucous membrane of the nose and that on the septum and in the meatuses, as well as on the turbinates, is boggy.

#### NECESSITY OF DIAGNOSIS

In treating allergic rhinitis, an exact diagnosis is essential. We have seen patients with edematous nasal mucous membranes in which at first glance we have thought it was allergic rhinitis. Some of these cases after being studied for a year and a half have proved not to be allergic. The only thing that brought about an improvement in the nasal condition was a proper diet plus adrenal cortex extract.

Rackemann<sup>12</sup> states that 50 per cent of the cases of vasomotor rhinitis are nonallergic. Cameron<sup>13</sup> of Glasgow puts it at 40 per cent. These percentages, as we view them, are very high. No one has ever proved that the cases of nonallergic vasomotor rhinitis were not at one time allergic. We had under observation a patient with allergic rhinitis who secured a most excellent result by the avoidance of certain allergens to which she was sensitive and by undergoing a submucous operation. Examination of the nose showed good breathing space; the turbinates, however, were paler

and softer than normal. The biopsy of the tissue taken after the treatment showed edematous tissue with no increase of eosinophils in the tissue.

Vasomotor disturbances in the nose may result from infection and inflammation. Even a simple irritation of the mucous membrane causes vasomotor changes. Clinically one must assume that there are many cases of vasomotor rhinitis which are not at the time of examination allergic. Further, it must be realized that many of these conditions will improve with treatment for dietary and endocrine defects.

Repeated attacks of acute allergic rhinitis leave behind a chronic vasomotor rhinitis. During the last year we have seen only one hay fever patient who had a normal mucous membrane. This patient had had only one attack of hay fever. The treatment of allergic rhinitis is so intimately tied up with the treatment of chronic vasomotor rhinitis that the two cannot be separated. We feel that every case of edematous nasal polyps and every case of chronic vasomotor rhinitis should have a complete allergic work up. We have not yet seen a case of edema of the mucous membrane presenting a great increase of eosinophils in the nasal discharge which did not prove to be allergic. On the other hand, we have all seen cases in which, with one or two or three studies of the nasal discharge no increase of eosinophils has been found but further study of the vasomotor rhinitis proved the case to be allergic and a good result was secured by allergic treatment.

Every case of boggy mucous membrane should have not only a complete allergic study but dietary, bacteriologic and endocrine studies. The first thing to do in the treatment of all cases of chronic vasomotor rhinitis is to correct the allergic condition if it is present. Dietary defects and endocrine disturbances should be corrected and infection should be eradicated. If this has been done there will be a certain percentage of boggy noses in which a good result can be secured only by some type of therapy applied to the mucous membrane of the nose.

One of the essential things in the treatment of allergic rhinitis is that the patient should be under the care of a rhinologist. The examination of the nose is necessary for a proper diagnosis. It is only by watching the nose that one gets the best idea as to the result of a given therapeutic procedure. Last and by no means least is the fact that one of the essential factors in the treatment of allergic rhinitis is to bring the nose into as normal a condition as possible. Infection of the nasal sinuses must be corrected. In perennial allergy we often get good results following the correction of deflected septums, the removal of exostoses or the removal of adenoids. Before very much was known about allergy it was known that cases of vasomotor rhinitis were often favorably influenced by the removal of adenoids in children. Most striking results often follow the correction of nasal lesions.

In cases of allergic rhinitis in which the biopsy has shown a typical allergic picture, complete subjective relief with objective shrinking of the mucous membrane of the nose has followed a submucous operation or the removal of adenoids. One might immediately ask the question How long will the patient be benefited? The question might well be answered by asking How long is a patient with allergic rhinitis benefited by desensitization or any other form of treatment? It is often necessary to eradicate a chronic vasomotor rhinitis in order to get the nose normal. In certain cases of

which a gonad tumor was responsible for the symptomatology. Laurie<sup>18</sup> has summarized the literature, finding eight instances in which pineal tumors seemed responsible for this syndrome. On the other hand, LeMarquand<sup>19</sup> reports a case in which a boy aged 4½ years had accessory brain tissue connecting with the hypothalamus. Because of these varying etiologic factors producing a similar picture, LeMarquand offers the following hypothesis: "In cases in which the pineal, adrenal, hypothalamus or gonads are involved, they each and all cause pubertas praecox by an influence on the hypothalamic centers and from thence on the pituitary."

Because of these links found in this chain of evidence, I believe that the statement made in the first paragraph of this paper, that vegetative regulation is the result of a most complicated interdependence between these two systems, is more than highly suggestive; therefore the visceral neurologist should have an understanding of the endocrine system, and likewise it becomes necessary for the endocrinologist to have an understanding of the visceral nervous system if the best clinical medicine is to be practiced.

812 Southwest Washington Street.

#### ABSTRACT OF DISCUSSION

DR. T. HOMER COFFEN, Portland, Ore.: It is always difficult to appraise contemporary medical thought and trends in a new field, often revolutionary and of absorbing interest, arousing clinical and laboratory investigation and gradually becoming established, with a united attack on it. Our modern concepts of diabetes, with resulting treatment with insulin, our modern concepts of cardiovascular disease leading to better understanding of coronary obstruction and angina pectoris, blood dyscrasia and the modern treatment of pernicious anemia with liver extract are the results of intensive investigation in recent years. All these, perhaps, will go down in history as of epochal importance. Fifteen years ago endocrinology was a field of intensive study. The special journal was voluminous, containing hundreds of contributions. By 1928 it appeared that the subject was almost a closed book. In the meantime, research on the visceral nervous system absorbed interest, and the attack was as intense as on the endocrine disturbances previously. More and more it became evident that there is an interdependence between these two systems. The revolutionary discovery of the gonadotropic hormone in the blood stream in recent years, resulting in a laboratory test for the diagnosis of pregnancy, sought for centuries, opened up many avenues of research and clinical correlation, so that today we find ourselves in a renaissance of interest in endocrinology, correlating its phenomena with the visceral nervous system. From the laboratory come astounding facts to be interpreted in clinical syndromes. One of these is the effort syndrome, or neurocirculatory asthenia. This syndrome presents symptoms of heart disease and disturbed circulatory function in the absence of heart disease. It masquerades to some extent under the guise of thyrotoxicosis, but there is no thyroid disease. It also presents symptoms of neurasthenia. The term effort syndrome acknowledges all these and makes it possible to pigeonhole these cases diagnostically. In the gastro-intestinal tract, pylorospasm or colon spasm are seen as a result of nervous tension exaggerated in some cases by thyrotoxicosis; here one may speculate on the possibility too of adrenal influence. Clinical observations certainly are of equal importance with laboratory experiments, and, from the evidence presented by Dr. Rush, it is perfectly obvious that there is a very definite interdependence between these two systems.

## MECHANICAL DECOMPRESSION OF THE SMALL INTESTINE IN ILEUS

### III. CLINICAL OBSERVATIONS WITH REPORT OF CASES

ALTON OCHSNER, M.D.

AND

AMBROSE H. STORCK, M.D.

NEW ORLEANS

The difficulty or impossibility of replacing tremendously or even moderately distended loops of intestine that have been either accidentally or intentionally eviscerated during operation for intestinal obstruction and the danger of producing "waterhose" kinks when rigidly distended intestine is forcibly replaced in the abdomen quite naturally led to the practice of evacuating the contents of distended loops by performing an enterostomy and "milking" or "stripping" out the intestinal contents at the time of operation (fig. 4). The use of stripping has been extended by some to the treatment of intestinal obstruction in which distention is only slight or moderate in degree. Those who have advocated the procedure under such circumstances have felt that the attendant beneficial effects were sufficient to warrant its use as a procedure of election. The practice of stripping the intestine under these less urgent circumstances certainly should not be justified unless it could be established that it is quite safe and not accompanied or followed by immediate or delayed undesirable effects and unless the results obtained are better than those resulting from simple relief of the obstruction.

Conflicting opinions concerning the merit and facility of operative evacuation of distended loops of small intestine have been expressed by clinicians of equal or comparably wide experience in the management of intestinal obstruction. Basing conclusions on their clinical observations and certain theoretical considerations and experimental data, one group strongly advocates such a procedure, whereas other clinicians unequivocally condemn it. The following references are of interest with respect to the development of the procedure and furnish some notable examples of the various estimates of this method of treatment. Monks<sup>1</sup> in 1903 demonstrated that almost the entire small intestine could be puckered or "gathered up" on a 1 foot long segment of a rod introduced into the intestinal lumen. Bottomley<sup>2</sup> credits Monks with suggesting the use of a glass tube introduced through an opening in the bowel for the purpose of evacuating the distended intestine, but, he adds, "in my own experience the successful employment of this procedure is not very easy." Holden<sup>3</sup> believes that the imprisoned intestinal contents above the obstruction should be removed at the time of operation for intestinal obstruction and Van Zwalenburg<sup>4</sup> says:

Does not the procedure of Holden seem reasonable and encouraging? By gently emptying the bowel he relieves the

## TREATMENT

After the completion of our study of the case, the treatment is the avoidance of allergens, desensitization, dietary measures, making the nose normal and, if it is indicated, endocrine therapy.

In connection with desensitization it is well to remember that if a person is made sensitive to one protein he may react to proteins with similar composition. In the same way, in desensitization, using an allergen may desensitize the patient to other allergens with a similar chemical composition.

Getting rid of the chronic boggy edematous nasal membrane that so often complicates allergic rhinitis is a very difficult matter. As we said before, ionization often gives good results. Hollender<sup>14</sup> has used ionization for ten years with good results in intumescent rhinitis.

Ionization may give a good result in patients with a maximum of chronic vasomotor rhinitis and a minimum of allergy. A patient suffered all the year round from nasal stoppage and sneezing. During the hay fever season she was confined to her bed. She worked in an atmosphere containing white flour dust. White flour gave a mild reaction in the nose; there were no reagins for white flour in her blood. The mucous membrane reacted violently to ragweed pollen. She had plus 4 reagins for ragweed in her blood. Ionization controlled her vasomotor rhinitis and gave her an excellent result until the next hay fever season, when she had as much trouble as ever. After the hay fever there was a partial return of her chronic vasomotor rhinitis.

Among other remedies the following have been recommended for the control of chronic vasomotor rhinitis: radium, the cautery, surgical diathermy, 95 per cent alcohol, concentrated phenol and 50 per cent trichloroacetic acid. A study was made of the action of each of these on the tissues with the hope that something as efficient as ionization with a less deleterious action might be found. All the agents mentioned that are said to be beneficial in chronic vasomotor rhinitis act by splinting the membrane. The resulting fibrosis keeps the membrane from swelling.

## RADIUM

A study was made of the use of radium in the treatment of nasal polyps and its effect on the nasal mucosa. Several authors have been prompted to use radium in the treatment of nasal polyps because of the fact that radium stimulates the formation of fibrous tissue. It has been a common observation that the more fibrous a polyp is found to be, the less are its chances of recurring after removal.

The first to use radium for this purpose was Sluder.<sup>15</sup> Others who used this method and modified it in various ways were Lyons,<sup>16</sup> McCullagh and Robinson,<sup>17</sup> Robinson<sup>18</sup> and Scal.<sup>19</sup> The general method used by these authors was to remove the polyps first and then, in from twenty-four to forty-eight hours, to place radium in the nose, using from 150 to 400 milligram hours. Lyons used 400 milligram hours three times (forty-eight hours, eight days and fifteen days after the removal of

the polyps) without noting any burning or other harmful effects. The aforementioned authors all found a delay in the recurrence of polyps and all stress treatment of the allergic condition or infection as the only means of complete cure. No detailed microscopic examinations were reported by these observers.

In order to study the changes brought about in edematous polyps by radium we placed 50 mg. of radium in each side of the nose of a patient, leaving it in place for four hours (total dose 200 milligram hours on each side). The polyps became diffusely reddened in three days and there was a profuse mucopurulent discharge. The edema of the polyps and adjacent mucosa was increased. This lasted for two weeks, at the end of which time the polyps were again pale and the same size as before treatment.

Polyps removed before radium treatment were covered by pseudostratified columnar ciliated epithelium lying on a thick pale basement membrane. The stroma was very edematous, and scattered through it were a few lymphocytes, plasma cells and eosinophils.

One week after radium treatment the epithelium was unchanged. The small blood vessels were engorged. In the spaces between the fibers of the reticulum in the stroma was an increased amount of fluid, which stained more deeply with eosin. A much greater number of plasma cells and lymphocytes were found in the stroma. The number of eosinophils was unchanged.

Three weeks after radium treatment, changes in the epithelium appeared. These cells lost their cilia, the nuclei became pyknotic, the cytoplasm was granular and numerous vacuoles appeared. The pseudostratified epithelium was reduced to a single layer of cuboidal cells. In the stroma were young fibroblasts in numbers sufficient to change its appearance entirely. Edema was still present, the fluid in tissue spaces now taking no stain. Plasma cells and lymphocytes were present in large numbers, the eosinophils remaining in the same numbers as before.

Thus we have definite evidence of a stimulation of fibrous hyperplasia in edematous polyps occurring two weeks after irradiation. In addition there is temporary edema and congestion, an increase in the chronic inflammatory cells infiltrating the stroma and destructive cytologic changes in the epithelium.

In order to study the end results of the action of radium on the nasal mucosa, 400 milligram hours of radium was used in one side of a dog's nose. In six weeks the dog was killed and serial sections were made of the snout.

At this point should be mentioned the work of Bernheimer and Cutler<sup>20</sup> and of Bernheimer.<sup>21</sup> They studied the action of radium on the allergic nasal mucosa of human beings and gave detailed microscopic observations and illustrations. The end result was one of fibrosis and loss of edema with no evidence of atrophic or infectious changes in the mucosa.

The only change noted in the dog at six weeks was fibrosis on the treated side. The tunica propria was the same thickness on the two sides but more dense on the treated side. Glands, epithelium, periosteum and vessels remain unchanged, although there may have been temporary changes present earlier.

a strong stimulus to intestinal secretion and in obstruction this must work in a vicious circle." In previous publications,<sup>17</sup> the investigations of Raine and Perry,<sup>18</sup> Henderson,<sup>19</sup> Hotz,<sup>20</sup> Usadel,<sup>21</sup> Hartwell, Hoguet and Beekman,<sup>22</sup> Murphy and Brooks,<sup>23</sup> Stone,<sup>24</sup> the Dragstedts, McClintock and Chase,<sup>25</sup> Gatch,<sup>26</sup> Van Beuren<sup>27</sup> and Hofmann<sup>28</sup> on the effect of distention on intestinal activity and vascularity have been discussed. Whereas theoretically the immediate relief of the intra-intestinal pressure and intramural strangulation by stripping of the intestine may seem imperative, it is important to determine the dangers of such a procedure and also whether the subsequent intestinal activity is as great as that which is present after the use of more conservative measures. Although one of us (A. H. S.) had used stripping of the intestine clinically in cases of mechanical ileus, it was considered desirable to obtain additional information concerning the value and dangers of the procedure by experimental observations. In previously reported experiments on dogs,<sup>17</sup> observations were made concerning the comparative effects of stripping of the intestine and simple relief of the obstruction in mechanical ileus. The results of one group of experiments<sup>17a</sup> corroborated Læwen's and Morton's observations as regards the depressing effect on blood pressures (fig. 2). In another group of experi-

stripping of the intestine, as might be surmised because of the relief of vascular disturbances but there was actually less activity than in those animals in which only simple relief of the mechanical obstruction was done (fig. 3).

#### ANALYSIS OF CASES

In sixteen clinical cases of intestinal obstruction stripping was used, and the present report is based on an analysis of these cases. All these patients were operated on between 1928 and 1931 before Wangenstein<sup>9</sup> suggested preoperative duodenal decompression, and probably at the present time many of the cases would not present the problem they did at that time. In this group is included one case of adynamic ileus of undetermined cause in which stripping was done in order to facilitate replacement of intestine and closure without causing kinking and because it was thought that immediate evacuation was advisable or even necessary as the only means by which the hydraulic vicious circle could be overcome and intramural vascular strangulation relieved at once. For the same reasons stripping was used in one case in which the preoperative symptoms and signs suggested the presence of a mechanical obstruction but in which at operation a severe enteritis was found, and in two cases of intestinal obstruction associated with peritonitis. As mentioned previously,

Cheever<sup>8</sup> also reports having employed the procedure in cases of intestinal obstruction associated with peritonitis. The causes of ileus in the other twelve cases were as follows: bands, three cases; carcinoma of the cecum, two cases; adhesions, fecalith, inguinal hernia, ventral hernia, volvulus, and obstruction due to constriction by an acute suppurative

gangrenous appendix, each one case. Stripping was employed also in one case in which the condition of the patient was very poor but in which immediate relief of intramural vascular strangulation by stripping in addition to performing a jejunostomy seemed imperative. The cause of obstruction in this last case was not revealed during the procedure of stripping, and further exploration was not considered advisable.

There were ten males and six females. Five of the patients were white and eleven were Negroes. The average age was 41 years, the oldest being 71 and the youngest 9 years old. The duration of the intestinal obstructions averaged 62.8 hours, with the shortest duration 24 hours and the longest duration 120 hours.

Cramping pain, nausea and vomiting were complained of in all cases except in the one presenting adynamic ileus. Stercoraceous vomiting occurred before or shortly after admission in five cases in which the average duration of obstruction was fifty-eight hours. Purgation before admission had been attempted in three cases, all of which ended fatally. Eight patients received enemas or flushes before admission, six of whom died and two recovered.

#### PAST HISTORY

There was a history of previous abdominal operation in seven cases, three of which were simple laparotomies. One was an exploratory laparotomy, one an

Fig. 2.—Kymographic tracing illustrating the fall in blood pressure caused by stripping the small intestine of a dog with intestinal obstruction of twenty-four hours' duration. The upper tracing indicates the periods of stripping and the other tracings show the blood pressure changes, the respiratory activity and the time intervals, respectively, from above down.

ments<sup>17b</sup> the intestinal activities twenty-four hours after either simple relief or stripping of the intestine in mechanical obstruction were determined. The duration of the mechanical ileus varied from twenty-four to 144 hours. It was found that not only was there no greater increase in intestinal activity following

brane and a serosanguineous discharge filled the treated nostril. There was hyperemia and edema to a lesser degree on the untreated side. Microscopic study showed the treated side to be partially denuded of epithelium, especially along the septum. In the recesses between the turbinates, ciliated epithelial cells persisted although the nuclei stained poorly and the cytoplasm appeared granular and cloudy. Cilia were still present. Strips of epithelium were seen to be separated from the tunica propria by serous fluid (bullae). The tunica propria contained massive areas of edema and extravasated blood. The vessels of the tunica propria were markedly engorged. The cells of the mucous glands showed cloudy swelling just as did the epithelial cells when present. No reaction was noted in the periosteum or perichondrium. Between the turbinates and the septum there was a thin serous fluid containing blood pigment and scattered polymorphonuclear neutrophils.

The untreated side showed hyperemia and edema of a small degree. There was some thin acellular serous fluid between the turbinates.

Cats killed three weeks after treatment with 70 per cent alcohol showed, on the treated side, masses of granulation tissue between the turbinates and the septum. This granulation tissue was deeply infiltrated with chronic inflammatory cells (polymorphonuclear neutrophils, lymphocytes and plasma cells). The epithelium covering the turbinates was for the great part missing and, when present, was of the stratified squamous type. The tunica propria was thick; its vessels were engorged. Nothing but skeletal remains of glandular epithelium was seen. The tunica propria was infiltrated with many chronic inflammatory cells. Deep in the turbinates, numerous islands of young proliferating bone could be seen.

The untreated side of the three weeks specimen was entirely normal except for a mild congestion of the small vessels.

At three months in the cats treated with 70 per cent alcohol the only gross difference noted in the treated and untreated sides was a thinning of the turbinates on the treated side. Microscopically, on the treated side, the epithelium was entirely of the stratified squamous type. Comparing the mucosa of the two sides, the treated side was found to be thinner and the tunica propria composed of denser fibrous tissue. The blood supply of the treated side was less; there were fewer glands. The bone and cartilage of the two sides were identical. The picture on the treated side was one of atrophy and fibrosis.

The instillation of 70 per cent alcohol in the noses of cats produced violent congestion and exudation with sloughing of the epithelium. This was followed by the formation of granulation tissue in the nose, a loss of glands, proliferation of bone and metaplasia of the epithelium. In three months' time definite atrophy of the mucosa had taken place.

At the suggestion of Dr. E. C. Bryce,<sup>22</sup> edematous nasal polyps were injected with 95 per cent alcohol, a tuberculin syringe and hypodermic needle being used, or the needle used in the clinic for making intramucosal tests.

Clinically a decrease in size of the polyps is seen as early as the day following the injection. In one instance, two days following injection of a medium sized polyp the patient returned with no polyp tissue visible to be removed for study.

The day after injection, a bright red spot is seen at the site of the injection. An ulcer may form at this

point. Part of the polyp sloughs off into the nose and the remaining stump shrinks up to form a small bud of tissue or disappears from sight in the meatus.

The usual pathologic picture of a polyp six or seven days after the injection of alcohol is demonstrated by this case. At the site of injection is an area of complete necrosis, the necrotic area being densely infiltrated with polymorphonuclear neutrophils. The tissue superficial to this area has sloughed off, leaving an ulcerated surface. Around the necrotic area is an area of hemorrhage into the tissues resembling the picture seen in an infarct. Outside this area the tissue is seen to be involved by coagulation necrosis, which diminishes in severity as one leaves the site of injection. Finally, an area of cloudy swelling is seen which may or may not include the remainder of the polyp, depending on its size and the amount of alcohol injected.

#### PHENOL

To study the action of concentrated phenol on the mucous membrane of the nose, dogs were used. Dogs were anesthetized with intraperitoneal injections of sodium amylal according to the method of Palmer;<sup>23</sup> their noses were swabbed on one side only with a concentrated solution of phenol. They were killed by air embolism at varying time intervals.

Those killed in two days showed grossly, on the treated side, a small amount of red exudate limited to the parts of the nasal cavity reached by the cotton swab. Microscopically the exudate was serosanguineous. In the region of the exudate the epithelium was denuded, the tunica propria was edematous and contained a small amount of extravasated blood, and the vessels were deeply engorged. Small areas of hemorrhage had separated the tunica propria from the periosteum. On the whole, the reaction was less violent than that seen in cats two days after instillation of alcohol into the nose. In areas not accessible to the phenol swab and on the untreated side, no change whatever was apparent.

Three weeks after the phenol swab was used, much of the epithelium was still absent from the treated side. Where present, it was ciliated. The mucous glands were merely dilated spaces in the tunica propria with no epithelial lining. The vessels were still dilated but did not contain much blood. The bone showed no change. The untreated side appeared normal, as it did at the two day period. Early atrophy with a retarded formation of the epithelium of the glands and mucous membrane seemed evident.

In the three month specimens the treated side was lined by stratified squamous epithelium. The tunica propria was fibrous but more vascular than the untreated side. The stratified epithelium was hyperplastic. Glands were present and appeared healthy. This is inconsistent with the picture of early atrophy seen at three weeks.

#### SUMMARY

Swabbing the nasal mucosa of dogs with strong phenol solution resulted in a partial loss of epithelium, a hemorrhagic exudate and engorgement of the mucous membrane limited to the areas in contact with the solution. In three weeks what seems to be early atrophy is present, but at three months there is a definite picture of fibrosis and hyperplasia. Palmer<sup>23</sup> reported that the essential change following the use of phenol was fibrosis of the nasal membrane.

23. Palmer, Arthur: *Ann. Otol., Rhin. & Laryng.* 44:25 (March) 1935.

nias, consisted of performing an enterostomy by introducing a No. 32 Pezzar catheter into the intestinal lumen and evacuating the intestinal contents by beginning in the region of the ligament of Treitz and stripping the entire small intestine. In order to prevent spillage, a single or double row of purse string sutures was employed to coapt the intestine tightly around the Pezzar catheter at the site of the enterostomy, and a moistened laparotomy sponge was held tightly pressed against the point at which the catheter entered the intestine. In order to minimize shock from the exposure of the intestine, the eviscerated loops of bowel were kept covered as much as possible by means of moist warm sponges.

Multiple intestinal obstructions were present in two cases. In one instance resection of the small intestine followed by side-to-side anastomosis was done. In one case with fixation of the ileum to the posterior abdominal wall with resulting angulation it was deemed inadvisable to attempt to detach the ileum, so an ileo-ileostomy was done. Appendectomy was done in one case in which the inflamed appendix lay across and compressed the terminal ileum.

Whereas in most instances the enterostomy tube was removed after evacuation of the intestinal contents and the opening in the intestine closed by a double row of sutures, in six instances the catheter was allowed to remain in place to serve as an enterostomy following operation. In three instances the catheter thus left in place had been introduced into the ileum and in two instances into the jejunum. In one case there was no record of the location or site of enterostomy. Also noteworthy in this last case is the fact that a Paul tube was used instead of a Pezzar catheter.

#### POSTOPERATIVE TREATMENT

A heat tent was placed over the abdomen of eight patients. In most instances it was allowed to remain in place for at least the first five or six postoperative days. Hot turpentine stupes were applied to the abdomen in one case.

Morphine was given postoperatively to eight patients. Fluids were administered subcutaneously and intravenously to all.

#### POSTOPERATIVE COMPLICATIONS

Postoperative adynamic ileus was recorded in two cases, in one of which survival occurred while death occurred in the other. Gastric dilatation was a postoperative complication in one fatal case. Acidosis (carbon dioxide combining power 23 volumes per cent) occurred postoperatively in one fatal case. Pneumonia (postoperative) occurred in one fatal case. Delirium and coma were each recorded as postoperative complications. All these patients except the one having postoperative delirium died. Two patients had infected wounds and one had an axillary cellulitis and cystitis, but these three survived.

An indwelling gastric catheter was employed postoperatively in twelve cases. In eight instances postoperative gastric lavage was performed and three of these patients lived, whereas five died. In two instances repeated aspirations through the Jutte tube was done, with one survival and one fatality. In two instances the tube was allowed to hang over the side of the bed for the purpose of permitting emptying of stomach contents by simple siphonage. Both these patients died.

The average stay in the hospital was thirteen days. Hospitalization in the survival cases averaged thirty-two days, whereas that in the fatal group was three and a half days.

#### MORTALITY

Of the sixteen patients in whom stripping of the intestine was done, five (31.2 per cent) lived and eleven (68.7 per cent) died. The average duration of obstruction in the group that lived was fifty-one and a half hours, whereas that in the fatal group was 68.4 hours. A mortality rate of 68.7 per cent is prohibitively high, but this probably cannot be considered as being due to the type of operation in all instances, because each patient in the group was a very poor operative risk when admitted to the hospital. Granted that the mortality rate in this group of cases would have been high irrespective of the procedure employed to relieve the obstruction, we believe that the additional trauma caused by intestinal stripping further aggravated the ileus and also caused surgical shock. At least the stripping, with its increased danger of infection, did not improve the condition of the intestine enough to lower the mortality rate. This belief is also corroborated by our experimental observations, in which it was demonstrated that the intestinal activity twenty-four hours after intestinal stripping was actually less than that in control animals in which there had been simple relief of the obstruction.

One death occurred on the operating table shortly after stripping the intestine, and in several instances the patients never recovered from the operative shock, which was precipitated or exaggerated by the stripping.

#### COMMENT

Whereas closure is facilitated and there is no immediate postoperative distention when the intestine has been emptied by stripping, we believe that the blood pressure lowering effect, the impairment of intestinal muscular tone and peristaltic activity, and the danger of peritoneal contamination incident to the procedure more than outweigh its good effects. For these reasons we contend that stripping should seldom be employed. Even when most carefully done, the necessary manipulation of the intestine causes considerable shock and local trauma, the latter being evidenced by subserous hemorrhages such as we have observed in some of our own cases, despite most careful handling of the intestine.

We believe that stripping is to be especially deprecated in cases of adynamic ileus without associated mechanical obstruction and in cases of mechanical obstruction with associated peritonitis.

We further believe that the institution of preoperative measures such as the replacement of electrolytes, administration of heat to the abdomen, administration of liberal doses of morphine, and employment of an indwelling gastric catheter attached to suction apparatus will in most instances relieve the excessive intestinal distention and intramural strangulation. Intestinal stripping is not indicated for a patient who has been so prepared. In the case in which relief of distention cannot be obtained preoperatively, we believe that stripping of the intestine should seldom if ever be done because, as shown by our clinical and experimental investigations, the results following stripping are no better than those following simple relief of the obstruction, whereas the untoward effects are greater following the former procedure.

interdependence of the visceral nervous system and endocrine system in the responses obtained. A similarity of action between epinephrine response and that of widespread sympathetic stimulation suggests that possibly epinephrine needs the same receptor as does the sympathetic nerve to obtain this response. This is further suspected when one considers Cannon's<sup>12</sup> long list of observations regarding the chemical mediator sympathin, a hormone apparently formed at the nerve ending and capable of giving epinephrine-like response to similarly sympathetic innervated tissue at a distant point. Burget and Zeller<sup>13</sup> have shown that the erosive lesions seen in the small intestine after parathyroidectomy are remarkably less frequent following vagus section. Davis prevented glycosuria and hyperglycemia by splanchnic section. Speculation now becomes tempting. One wonders whether possibly all hormones act by way of the visceral nervous system, particularly their receptors, or are hormones needed for certain visceral nerve responses.

4. The visceral nervous system is affected by the endocrine system. This conclusion is supported by the ingenious work of Cushing.<sup>14</sup> He has observed in the human being that the injection of solution of posterior pituitary intraventricularly produces a response, apparently stimulatory, characterized by widespread vasodilatation, sweating, vomiting and lowering of the body temperature. He further noted that this response could not be obtained in the presence of a lesion which impaired the functional activity of the interbrain, more particularly the hypothalamotuberal portion or after the administration of atropine or the use of tribromethanol, a hypnotic which supposedly acts on the diencephalon.

A second example is afforded by the experiments of Marine,<sup>15</sup> who observed a progressive exophthalmos in young rabbits by the use of cyanide. They believe this phenomenon not the result of thyroid activity but of an increased amount of thyrotropic substance coming from the anterior pituitary, which stimulated sympathetic centers in the hypothalamus. They were able to control the exophthalmos by iodine or thyroxine administration and suggest that a delicate physiologic balance between thyroxine and the thyrotropic principle must be needed.

Clinically, examples are quite numerous to show the effect of glandular dyscrasias on the psychic response of a human organism. Thus, in hyperthyroid activity, apprehension is usually seen; in myxedema, mental sluggishness and emotional torpidity; in tetany, anxiety; in Addison's disease, mental fatigue, and during the menopause or after spaying, mental depression and emotional instability. This array of psychic disturbances is similar at least to the emotional imbalance of the anxiety tension state and is likewise associated with visceral nerve disturbance functions. Thus are seen changes in heart rate, changes in vasomotor response, changes in intestinal activity and changes in sweat gland activity, as well as other symptoms. Who knows how much of this is produced by a direct effect

from the disturbed hormone function and how much is produced by the disturbed visceral nervous system?

Jelliffe<sup>3</sup> reports in great detail the case of a housewife who complained of nervousness, tachycardia, increased perspiration and fatigue, giving, in fact, the symptoms of exophthalmic goiter, which condition was diagnosed. However, with painstaking care it was shown that this case belonged in the group of anxiety tension states and her clinical cure was the result not of thyroid therapy but of psychotherapy with relief of the tension state. Such a case is not uncommon and the differential diagnosis may be extremely difficult because of the interdependence of these two systems.

The following is a brief report of a case that came under the observation of the surgical staff at the University of Oregon Medical School:

A male adult Negro was admitted to the Multnomah County Hospital with a distinct exophthalmos and the customary signs and symptoms of exophthalmic goiter. A subtotal thyroidectomy was performed, following which the symptoms subsided. The patient was not seen again for about six months, at which time he again presented himself with the signs and symptoms of a thyrotoxicosis. His exophthalmos had become more marked, his basal metabolic rate was again high, nervousness and tachycardia were present, but, most bothersome of all, there was a pyloric obstruction, which was verified by x-ray studies. Approximately 1,500 cc. a day was aspirated from his stomach. The patient also complained of intermittent claudication in both arms; that is, muscle pain brought on by exercise and relieved by rest. The gastro-intestinal problem became so acute that the surgical staff contemplated the necessity of emergency surgery for feeding. However, it was finally decided to attempt the thyroid surgery first, and a second subtotal thyroidectomy was done. Following this operation the gastric retention rapidly subsided, being about 300 cc. the following day; it dropped to 150 cc. the next day or so and, after a few days, aspirations were no longer necessary. X-ray examinations were repeated and the pyloric obstruction had entirely disappeared. The intermittent claudication which involved the arms also disappeared, although the exophthalmos progressed and became a very troublesome condition.

This case exhibited three pronounced symptoms that are usually interpreted as of visceral nervous origin; namely, the exophthalmos, the pyloric spasm and the intermittent claudication. Two of these entirely disappeared following an endocrine operation; namely, thyroidectomy.

Some clinical entities seem to be caused by either a lesion of the visceral nervous system or an endocrine dyscrasia. Clinical syndromes are present which may have either an endocrine etiology or a visceral nerve etiology. This conclusion is well demonstrated by the varying opinions offered as to the cause of Fröblich's syndrome, diabetes insipidus, certain disturbances in carbohydrate metabolism, thermoregulation and pathologic sleep. Apparently the hypothalamic pituitary mechanism is involved in these conditions and at times medical thought has been swayed toward the endocrine side and at times toward the neurologic side.

Perhaps the most classic example is that of pubertas praecox, an unusual clinical entity which has attracted interest over the years. Lissner<sup>16</sup> reports a case in which a boy showed this syndrome; an adrenal cortical tumor was found and successfully removed, with some regression of signs and symptoms. Sutherland<sup>17</sup> reports a case in a boy with similar signs and symptoms in

lost by vomiting in the high obstructions. Adequate and aseptic decompression is the only therapeutic measure that can favorably influence the low obstruction.

DR. ALTON OCHSNER, New Orleans: I didn't give Dr. Gatch credit for his contribution on the importance of intra-enteric pressure. This is something which has not been sufficiently appreciated in the past. Van Zwalenburg was the first to call attention to it. Wilkie has emphasized the importance of it in the obstructive type of appendiceal disease, and Gatch and his co-workers have done a great deal with this work. I agree with Dr. Gatch that enterostomy is seldom necessary with the use of these other preoperative measures, particularly the trans-duodenal decompression and the use of large doses of morphine. We have been using oxygen for a number of years, believing that it prevented anoxemia in individuals who receive large doses of morphine. Dr. Fine of Boston has shown recently that the inhalation of oxygen is of distinct benefit in aiding in the elimination of gas from the intestinal lumen, and I am sure that the results obtained from the inhalation of oxygen is largely due to this mechanism. The individualization in these cases is of the utmost importance, and there is no set rule that can be laid down. Possibly there still will remain some few cases in which a general "stripping" might be necessary, but they certainly represent the exception and not the rule.

## ANOMALIES AND FRACTURES OF THE VERTEBRAL ARTICULAR PROCESSES

WILBUR BAILEY, M.D.  
LOS ANGELES

Fissures across the vertebral articular processes may be formed by the presence of an ununited accessory center of ossification opposite the tips of the articular processes, or they may be the result of fracture of the articular processes. The differentiation between these anomalies and isolated fractures of the vertebral articu-

Fig. 1 (case 1).—H. H., aged 40, a laborer, fell from a scaffold, complained of transient numbness of the extremities and pain in the back. Symptoms disappeared soon. Anomalous fissure formation through tips of both inferior articular processes of second lumbar vertebra.

lar processes can nearly always be made, but even in the literature considerable confusion exists in making the distinction, and anomalies have been mistaken for fractures. If proper value is given to the history of the injury and to the appearance in the roentgenograms, such mistakes are preventable.

### ANOMALIES

Much more common than fractures are the fissures due to anomalies which arise because of an accessory

center of ossification opposite the tip of an articular process in the lumbar region. Such fissures are usually transverse, well demarcated and often bilateral or multiple. There are, however, variations which are shown in the present series of cases and which depend for their appearance on whether or not partial fusion has occurred between the accessory center of ossifica-

Fig. 2 (case 1).—Lateral view. The anomalous fissure formation can often be seen in this position.

tion and the tip of the articular process and, if so, how much. The commonest location is at the tips of the inferior articular processes of the second and third lumbar vertebrae, but nearly any lumbar vertebra may be so affected, as is indicated by the present series of cases.

The etiology of this anomalous fissure formation has been attributed by various authors to at least three possibilities. Müller<sup>1</sup> first considered these fissures as "umbauzonen" by which he meant to imply that they were like the fairly well delineated areas of rarefaction which he had found in spinous processes that bordered on a tuberculous lesion in the spine. In this and other locations in which there was abnormal strain on a spinous process, the bone of the process reacted by

Fig. 3 (case 2).—G. B., aged 28, a laborer, gave a history of having wrenched the lower part of the back while lifting. Persistent pain in the lower part of the back. Anomalous fissure at right inferior articular process of second lumbar vertebra.

showing a well delineated transverse line of rarefaction. At a slightly later date, Grashey<sup>2</sup> called attention to this articular process fissure phenomenon and described

Read before the Section on Radiology, at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1934.

circulation, restores normal capillary function more promptly, and removes toxic and infective material. Prompt restoration of adequate circulation is the important result. It is obvious that he must avoid trauma. When carefully done, there should be little shock from this procedure.

According to Moynihan:<sup>5</sup>

No operation for acute obstruction can be considered complete which leaves an intestine, whose function it is to absorb, overdistended by contents of an offensive and poisonous nature. To empty the bowel of its feculent contents is not to add a danger to the operation by reason of the opening and subsequent suture, but to remove, at the cost of a trifling expenditure of time, that condition which makes most speedily for failure.

Although Moynihan<sup>5</sup> does not advocate stripping, he suggests that evacuation of the bowel be accomplished by drawing the distended bowel on to a long glass enterostomy tube, a procedure which in practice frequently involves at least almost as much manipulation of the intestine as does stripping. Cheever<sup>6</sup> contends that the need for the immediate relief of distention is so great that evisceration and evacuation of the contents of the intestine, both in mechanical obstruction and even in some cases of ileus associated with peritonitis, should be done. On the other hand, Låwen<sup>7</sup> showed that the trauma associated with intestinal stripping results in cardiovascular disturbances, particularly fall in blood pressure, and Morton<sup>8</sup> contends that emptying of a distended loop of toxic material, even by the slightest manipulation, causes damage to the friable mucosa, hemorrhage and absorption of toxin. He thinks that stripping the intestine is a very dangerous procedure and has evidence that it acts the same in human cases as it does in animals. Stripping of normal intestine causes carotid blood pressure to fall, but it recovers and in forty-five minutes is normal. When the same thing is done after an ileus of twenty-four hours' duration, he says, the blood pressure falls and shows little tendency to return. A proportion of these animals quickly die.

Whereas the theoretical advantages of relieving intra-intestinal pressure and dilatation of the intestine in ileus cannot be denied, especially when one considers the possibility of accompanying intramural strangulation, it is necessary by careful clinical and experimental investigations to evaluate the advantages of mechanical stripping of the intestine. The intelligent use of duodenal decompression preoperatively, as suggested by Wangenstein,<sup>9</sup> usually will obviate the necessity of such a procedure, but still there are cases in which such preoperative measures are contraindicated or unsuccessful and in which stripping might be used.

In any attempt to evaluate the procedure, some pertinent laboratory and experimental observations must be considered. Blalock<sup>10</sup> states that:

One of the most frequently used methods of producing shock experimentally consists of traumatizing the intestines. In experiments on twelve dogs, this was done by passing the intestines gently [italics ours] between the fingers. This was continued until a sustained low blood pressure resulted.

Dragstedt, Lang and Millet<sup>11</sup> have shown that there is considerable variation in the intramural blood supply of various parts of the intestine and, owing to this anatomic variation, intra-intestinal pressures exert varying influences on the blood supply (fig. 1). Kocher<sup>12</sup> in 1899 showed that intra-intestinal pressure might interfere with circulation and cause gangrene of the intestinal wall, and Van Zwalenburg<sup>13</sup> made observations on blood flow in the intestinal wall as affected by varying pressures within the intestinal lumen. The latter concluded:

The demonstration seems complete that distention of the gut (or of other hollow viscera) interferes with the circulation in its wall and allows infiltration and effusion to take place into its wall and lumen and any other open spaces which may come within its influence. The return circulation is retarded at comparatively slight pressures. Effusion follows, as in all obstructions to venous flow. As the average venous pressure in the intestine under ordinary circumstances probably varies from 4 to 10 mm. of mercury, any pressure beyond that will offer some resistance to the return current.

Gatch, Trusler and Ayers<sup>14</sup> showed that the blood flow through the intestinal wall decreased as the distention increased and ceased when the pressure within

Fig. 1.—Diagram showing the relative points at which the vasa recta pierce the muscular coat at different segments. Distention occurring in the higher levels more readily causes compression of the blood vessels against the muscular layer, producing intramural vascular strangulation. (Modified after Dragstedt, Lang and Millet<sup>11</sup> and Morton.<sup>9</sup>)

the intestine equaled the systolic blood pressure. Burget, Martzloff, Suckow and Thornton,<sup>15</sup> working with subcutaneous, closed intestinal loops with intact mesenteries, showed that no clinical manifestations developed unless the pressures in the loops were high and produced vascular disturbances. Morton<sup>8</sup> found that the duodenum secreted from five to ten times as much fluid as the ileum and that, whereas the normal intra-intestinal pressure varies from 2 cm. to 4 cm. of water, after twenty-four hour obstruction the pressures within the duodenum and ileum increase from 28 cm. to 36 cm. and from 4.5 cm. to 5 cm., respectively. Herrin and Meek<sup>16</sup> studied the effect of distention on dogs with varying types of fistulas. They state: "Distention is

the right inferior articular process of the fourth lumbar vertebra and the adjacent superior articular process of the fifth lumbar vertebra were fractured.

Dohan<sup>11</sup> in 1910 recorded a case in which the right superior articular process of the sacrum was fractured and Graessner<sup>12</sup> in 1912 mentioned three similar cases as having been found in a series of various types of

Fig. 7 (case 5).—W. H., aged 77, a physician, with no history of trauma, complained of enlargement of prostate. Oblique anomalous fissure in the right inferior articular process of first lumbar vertebra.

spinal injuries. There are several other similar reports in the old German literature. Lippens and Dejardin<sup>13</sup> in 1932 recorded three cases in which the articular processes of the fifth lumbar vertebra were believed to be fractured. It was not until 1933, however, that a clear-cut case was demonstrated by Mitchell<sup>9</sup> in a report to which reference has already been made.

In view of the frequency with which an apparent fissure formation may be simulated, especially in the lumbosacral region, when two articular processes overlap because the lateral articulations are in an oblique plane, it becomes apparent that some of the reports of fractures, especially before the present advances in radiologic technic, may not be well founded. It seems also true, however, that articular process fractures may

Fig. 8 (case 6).—Miss M. K., aged 26, a secretary, with no history of trauma, complained of indigestion. Anomalous oblique fissure formation in the right inferior articular process of first lumbar vertebra. Note notching in the humeral process of the twelfth thoracic vertebra.

sometimes be overlooked because the plane of the fracture is not seen in the usual routine view. The importance of radiographic exposures in the oblique as well as in the lateral position cannot be overempha-

sized as a means of thoroughly examining the lateral articulations and articular processes.

Both the case reported by Burk<sup>14</sup> and the one reported by Koch demonstrate the importance of the history, the mechanism of the trauma and the severity of the after-effects in cases of true fracture. Burk's 30 year old patient, in an effort to put heavily loaded platters on a low cabinet shelf near the floor, was squatting with her spine flexed forward when a sudden and severe twist of the spine toward the right was occasioned by her efforts. She promptly felt a sharp pain in the lower part of the back and could no longer stand completely erect. A year and half later she was still unable to bend over or lift heavy objects. An x-ray examination showed an exactly sagittal fracture fissure, which separated off a small fracture fragment through the right inferior articular process of the fifth lumbar vertebra. (The plane of the lumbosacral articulation in this case was so oblique as to be almost frontal). Operation showed the lateral lumbosacral joint space to be obliterated and motion to be occurring at a pseudo-arthritis between the fracture fragments. Although there had been much attempt at callus forma-

Fig. 9 (case 7).—J. B., aged 21, a laborer, strained his back six months prior to examination by falling over a box. Injured same place again by overreaching. Incomplete anomalous fissure at tip of right inferior articular process. Note also anomalous failure of fusion of the spine of the fifth sacral segment.

tion, no actual union had occurred. Two months after operative removal of the fracture fragment the patient was entirely well.

Koch's patient was flexed forward helping other men lift an anchor when another laborer shoved him sideways. A terrific pain immediately developed in his back and the patient became unconscious for a short time as a result. This is another instance of a patient who was seriously crippled until the fracture fragments (tip of the inferior articular process of the right fourth lumbar and adjacent superior articular process of the right fifth lumbar) were removed.

Both these cases show clearly that mere flexion and extension of the spine never cause such fractures, but such motion, if there is also a sideways twist, especially if a component of rotation is added, will be sufficient to cause trouble if the amount of motion is more than physiologic. Under such conditions the ligamentary pull plus the abnormal leverage of the articular processes against one another are the factors that may be sufficient to cause fractures. The factor of ligamentary pull is important in diagnosis, for the fragment is often by this mechanism pulled away from its point of attachment and does not lie in close apposition to

appendectomy and one an umbilical hernioplasty. The length of time elapsed since the previous operation varied from two days to fifteen years. There was a definite history of previous peritonitis in two cases, caused in one instance by a ruptured appendix and in the other by pelvic disease. One patient gave a history of severe trauma to the abdomen thirty years previously.

#### SIGNS

Abdominal distention was severe in most of the cases and in one of the cases presenting adynamic ileus was of such degree that there was no abdominal movement during respiration. In several cases the abdomen presented a corrugated appearance owing to the underlying distended loops of intestine.

Tenderness of the abdomen was noted in nine cases and abdominal rigidity was present in four cases. Both these signs were present in one of the cases in which there was associated peritonitis.

Peristaltic activity was audibly or palpably detected in five cases.

The average preoperative temperature was 99.3 F., with a range from 97.2 to 102.6 F. The preoperative pulse rate averaged 99 beats per minute, with a range from 52 to 140.

The average respiratory rate was 26 per minute, with a range from 20 to 40 per minute.

#### LABORATORY EXAMINATIONS

Pronounced concentration of the blood, indicated by high red blood cell counts and high hemoglobin values, was observed in four cases, all of which ended fatally. The carbon dioxide combining power of the plasma for the entire group averaged 50.3 volumes per cent and varied between 76 and 26 volumes per cent. Both patients who manifested these extremes of carbon dioxide combining power lived. There were four cases in which the carbon dioxide combining power was above 50, and three of these patients died. The carbon dioxide combining power was below 50 volumes per cent in four cases, two of which ended fatally.

The blood nonprotein nitrogen was above 30 in eleven cases, the values varying from 34 to 300 mg. per hundred cubic centimeters of blood. The average nonprotein nitrogen in the survival group was 56 and that in the fatal group 133. The highest nonprotein nitrogen recorded in a survival case was 87.

Blood chloride determinations ranged from 363 to 774, with an average of 472 mg. per hundred cubic centimeters of blood. The average blood chloride content in the survival group was 587 mg. and that for the fatal group was 469 mg. per hundred cubic centimeters.

Albumin was present in the urine in five cases in the entire group. Only two of the patients having albumin in the urine lived. Pus cells were present in the urine of two patients, both of whom lived. Casts were present in four cases, three of which were fatal. Indican was present in one case, and this patient died.

Preoperative x-ray studies consisting of plain films taken with the patient either erect or lying on the side were made in nine cases. Four of these patients lived and five died. Barium sulfate enemas were not employed in any of these cases and in none of these was barium given by mouth. The average amount of time elapsing between the onset of obstruction and the making of the x-ray examination was fifty hours. Diffuse gas accumulation was noted in two cases, both of which were fatal. In no instances in this group were

localized accumulations of gas alone found. There were localized or moderately pronounced fluid levels in two cases, in both of which survival occurred, whereas in six cases in which fluid levels were pronounced and diffuse there were five deaths and only one survival. In only seven of the nine cases in which plain plates were made was the extra evidence of obstruction quite definite.

A small stomach tube or Jutte tube was introduced preoperatively in twelve cases. In seven of these cases gastric lavage was done. In one case the tube was aspirated at intervals and in four cases the tube was simply allowed to hang over the side of the bed to permit evacuation of stomach contents by simple siphonage. Ten of the patients on whom some type of preoperative gastric drainage was done died and two lived. Hypodermoclysis or phleboclysis was used preoperatively in each case.

#### ANESTHESIA

Spinal analgesia was employed in eight cases with six deaths. In seven of these cases procaine crystals dissolved in spinal fluid were used and in one instance a preparation of procaine with strychnine sulfate was

Fig. 3.—Comparison of the degree and character as well as of the duration of intestinal activity in ileus treated by simple relief of obstruction and by relief of obstruction plus stripping. The black area denotes the average increase in tone in millimeters, the vertical shading the average increase in amplitude in 0.1 mm., and the oblique shading the average duration of activity in minutes.

used. Local analgesia was used for four patients, all of whom were in extremely poor condition, with three deaths. Ether was administered to three patients with one death. One patient who received ethylene anesthesia died.

#### OPERATIVE RESULTS

A definite and complete absence of peristalsis was recorded in two cases, both of which were fatal. Discoloration of the intestine was present in four patients, only one of whom survived. Mesenteric thrombosis was present in one fatal case. An excessive amount of clear peritoneal fluid was recorded in one fatal case, but this finding was present in several other cases in which no specific notation of such a condition was made. Peritonitis was present in three patients, one of whom survived. Edema of the intestine was definitely recorded in only one fatal case. The degree of distention, recorded as 1, 2, 3 or 4+, averaged for the entire group 2.8+. The average degree of distention for the survival cases was 2.6+, whereas that for the fatal group was 3.0+. The average duration of operation in seven cases in which it was recorded was sixty-five minutes.

#### OPERATIVE PROCEDURE

The operative procedure used, aside from division or resection of bands and adhesions or reduction of her-

Since eight of the present series of ten anomaly cases were selected from 2,000 cases in which a radiographic examination of the spine was conducted, it seems likely that such anomalies are more common than would appear from the literature. As previously noted, isolated fractures of the articular processes are quite rare.

#### CONCLUSIONS

1. The chief importance of fissures across the vertebral articular processes lies in the differentiation of anomalous centers of ossification at the tips of the articular processes from isolated fractures of the articular processes.

2. Such accessory ossicle formation is not very unusual. The history of antecedent trauma may be vague or entirely absent, as it was in over half the cases in this series; the defect is often bilateral, and the inferior, and very rarely the superior, articular processes are affected.

3. Fracture of the articular processes without severe concomitant injuries of the spine is a rare lesion. The mechanism is understood and the history should conform to it; the pain is prompt, severe and disabling; the fragments are usually displaced, owing to ligamentary pull; the fracture fissures are characteristically irregular and a small comminuted fragment may be produced.

Los Angeles General Hospital.

### ANOMALOUS BONES OF THE WRIST AND FOOT IN RELATION TO INJURY

W. WARNER WATKINS, M.D.

PHOENIX, ARIZ.

Compensation for industrial injury has become one of the major problems of our social organization, and the treatment of injuries under various forms of industrial insurance is probably the largest single field in the practice of medicine. Among the injuries sustained by workmen, those which involve the hands make up the largest group, and those involving the foot are a close second; the two combined probably comprise 50 per cent of the aggregate of industrial accidents. The manual laborer or machine operator whose hand is crippled is disabled until his injuries have healed and function has been restored. Injuries to the feet which interfere with weight bearing and locomotion are nearly as serious.

The evaluation of an industrial injury is largely influenced, perhaps too much so, by the presence or absence of bone lesions. Consequently, a knowledge of the anatomic variations in the bones and joints becomes a very essential part of the training of a physician for industrial practice. There are many bony anomalies in the body, but my aim in this paper is to confine its discussion to the principal extra bones that are found in the wrist and foot and that cause confusion in interpreting roentgenograms and evaluating injuries to those important joints.

#### WRIST

Dwight lists twelve anomalies represented by distinct supernumerary bone formations in and about the wrist.

any one of which can be mistaken for fracture. Several of these are rare and have not been seen in my experience.

1. Probably the most troublesome anomaly in the wrist, so far as the industrial surgeon is concerned, is the divided scaphoid (navicular) bone. Like the other carpals, this bone usually ossifies from a single center but may develop from two centers, and these may fail to fuse. In a considerable number of wrists, evidence of incomplete fusion may be observed on films (fig. 1) and occasionally the bone will be found divided into two fragments, usually of unequal size. Dwight cites a case, diagnosed as fracture, in which a careful histologic examination was made and two distinct bones with a cartilaginous plate between were shown to exist. Closely akin to this, but less frequently seen, is the divided semilunar (lunate). These two bones in their articulation with the os magnum (capitate) form the keystone of the wrist joint. The clinical importance of a divided scaphoid (or semilunar) is that the condition represents a mechanically faulty construction. Dislocation forward on the os magnum occurs more readily, a situation hardly compensated for by the fact that reduction can be more easily accomplished than is otherwise the case. The line of division in a subdivided scaphoid or semilunar is not a true joint, and trauma is usually followed by bone reaction along this line of junction. Such a reaction is difficult to distinguish from that which occurs in traumatic fracture with an abortive attempt at union. When a person with such anomalous conditions in the wrist attains full growth and enters an occupation that subjects the joint to strenuous use and repeated trauma, the first x-ray examination thereafter is very likely to reveal a dense and devitalized bone—the typical Preiser or Kienböck lesion. It is quite obvious that the management of a case of congenitally divided scaphoid, or one that has been divided by some old injury, should be quite different from a case of recent fracture. Therefore the proper interpretation of the conditions shown by x-ray becomes of paramount importance.

2. The industrial surgeon and the roentgenologist meet a somewhat similar situation in the interpretation of the os triangulare or ununited styloid process of the ulna. The existence of an additional bone distinct from the styloid process (fig. 2) is said to be rare, but it seems purely academic whether the detached fragment is an extra bone or an ununited styloid epiphysis. I am quite certain that I have seen instances of both types of anomaly, and the condition occurs often enough to be a matter of importance to industrial surgeons in determining whether the separate fragment found by x-ray examination following an injury to the wrist is a true anomalous bone, an old fracture with nonunion, or a recent fracture. When found associated with Colles' fracture, it is not of major importance because it will be repaired by bony or fibrous union by the time the fracture of the radius unites. It is when the separate styloid is the only suggestive finding that it becomes important. Correct interpretation requires a high degree of technical skill in producing suitable films and critical judgment by the roentgenologist in drawing conclusions. I have seen many wrists in which I am quite certain that the separate fragment has never been united, others in which fracture was definite and still others in which a single examination was not conclusive.

From the Pathological Laboratory.  
Read before the Section on Radiology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

## SUMMARY AND CONCLUSIONS

1. The relief of intestinal distention in mechanical and adynamic ileus is desirable because of the beneficial effects of such a procedure on the blood supply of the intestine.

2. Stripping of the intestine during the operative relief of the obstruction will empty the intestine of its contents.

3. As shown by clinical and experimental observations, this procedure is attended with considerable risk, especially the danger of producing shock, contamination and injury of the intestinal wall.

4. The ultimate activity of the intestinal musculature is no better and in experimental observations is actually less marked in those cases in which stripping has been used than in those cases in which simple relief of the obstruction is employed.

5. Careful preoperative preparation of patients with ileus by means of duodenal decompression, replacement of electrolytes, and liberal doses of morphine in most cases will relieve the excessive intestinal distention and intramural strangulation.

1430 Tulane Avenue.

## ABSTRACT OF DISCUSSION

DR. WILLIS D. GATCH, Indianapolis: The value of this paper is in the exposition of the disastrous results of radical operation for advanced bowel obstruction. The intestinal mucosa possesses a power of selective absorption, which enables it to permit the passage into the blood of substances beneficial to the body and to prevent the entrance of poisonous materials. Many substances produced by the action of digestive ferments of bacteria on the contents of the normal or obstructed bowel are intensely toxic when introduced directly into the blood stream. The mucosa holds them back. It does so in the presence of intestinal obstruction as long as it is alive and uninjured. The operation of bowel stripping must certainly injure the mucosa and thus cause the absorption of toxic material. The complete drainage of this material by the operation is obviously impossible. The chief cause of the appalling death rate of intestinal obstruction has been the practice of subjecting patients to radical operation before they have been properly studied and prepared. Our present knowledge of bowel obstruction justifies the conclusion that the condition of a patient with intestinal obstruction is never so urgent as to justify the omission of complete preoperative study and treatment. This applies especially to the apparently advanced cases. They should not be treated as immediate surgical emergencies. I suggest the following plan of management: 1. The administration by intravenous injection of enough salt solution and dextrose to relieve dehydration and lack of nourishment. 2. Continuous gastric lavage by means of a nasal tube connected to a siphoning apparatus. 3. A thorough diagnostic study of the case, including a roentgenogram of the abdomen taken after the administration of a barium sulfate enema. If it is at all possible, the cause, site and state—whether early or late—of the obstruction should be determined. 4. The administration of enough morphine to relieve the patient of pain and apprehension. Morphine causes tonic contraction of the bowel and thus aids its decompression. These measures can be carried out simultaneously without disturbing the patient or removing him from his bed. This treatment will produce a great improvement in the condition of all but moribund patients. It is sufficient to relieve the obstruction in many instances. In all cases it will at least make the patient a much better operative risk. The treatment outlined has been planned to correct the local and systemic derangements caused by bowel obstruction. It reduces the peril of radical operation by deferring it until the systemic circulation is normal, until the site and cause

of the obstruction are fairly well known, and until the danger of manipulating distended and fragile loops of bowel is past.

DR. OWEN H. WANGENSTEEN, Minneapolis: I find myself in accord with the expressions of the authors. My displeasure with the method of stripping the bowel arises largely from the inability of preserving absolute asepsis throughout such a procedure. The most fundamental requisite for a successful issue is that the sterility of the peritoneum be preserved inviolate. The minutest escape of intestinal contents is synonymous with failure. The forbidding mortality of the operative treatment of bowel obstruction is due in large measure to lack of regard for the importance of this factor. The time has come to speak of the mortality of the disease and the mortality of treatment. My practice in dealing operatively with late cases of simple obstruction has been to do an enterostomy; it has been my experience that, if a vent for drainage can be established in this manner without spillage, a successful issue can be predicted. Operations of election are not well tolerated by patients with acute obstruction. An x-ray film of the abdomen gives reliable information as to where the obstruction will be found. Similarly, in the colon, aseptic decompression is the first considera-

Fig. 4.—Method employed to empty the small intestine by stripping after introduction of a Pezzar catheter, the eyelets of which have been enlarged.

tion. Such patients are to be identified preoperatively by the great distention frequently unaccompanied by vomiting and by the absence of gastric retention. The x-ray film indicates the degree and extent of the distention. I decompress such patients through a short transverse incision made directly over the transverse colon. As the authors have said, a number of patients may be satisfactorily managed without recourse to surgery, through the employment of suction applied to an inlying duodenal tube. In the main, however, the use of this therapeutic expedient as a sole therapeutic agent must be limited to instances of physiologic and adhesive types of obstruction. In its employment it is necessary to exclude instances of acute obstruction of the colon with great distention as well as strangulating types of obstruction. It is also important to follow the progress of the distention with subsequent x-ray films to be certain that the bowel is actually being decompressed. The need for the administration of enough para-oral fluids to insure an adequate daily urine output (from 700 to 800 cc.) is obvious. The significance of distention in the ill effects of bowel obstruction and the importance of decompression as a relief measure have become so apparent that I believe the time has come to change the adage concerning the danger of the high obstructions to read: The low obstructions are the most serious, for they carry the greatest hazard for the bowel wall. In saline solution, a good substitute is available for the fluids

tibialis posterior muscle is inserted into this tuberosity and is one of the chief muscles of plantar flexion, a forcible dorsiflexion might, and no doubt often does, rupture this attachment and along with the tendon injury may detach a fragment of bone. The surgeon and roentgenologist frequently have the responsibility of differentiating between an actual fracture and an unfused tuberosity. Roentgenograms of the opposite side do not help much, as Pitzner is said to have found the anomaly unilateral in more than one third of his observations. Examples of the sesamoid type, as well as various sizes, shapes and degrees of union of the tuberosity, are frequently seen; sometimes it is subdivided. It is readily understood how an x-ray examination taken two or three weeks after a foot injury, such as dropping a weight on top of the foot, may show such a detached bone fragment, which can easily be interpreted as a fracture, and it is usually the responsibility of the roentgenologist to say positively that such a condition is or is not a fracture.

3. *The Os Peroneum*.—This is the most commonly observed extra bone in the foot, and probably the least important. It is a sesamoid bone in the tendon of the peroneus longus where that muscle grooves the cuboid bone. Its position varies considerably, sometimes well forward under the cuboid, at other times more posterior beneath the head of the os calcis (calcaneum) or in an intermediate position under the calcaneocuboid articulation; it also varies much in size, shape and density and may be subdivided. Though of less clinical importance than some other anomalous bones, cases have been encountered in which dispute and confusion have arisen over this bony fragment.

4. *The Os Vesalianum Pedis*.—This bone corresponds to the bone of the same name in the hand, being the unfused tuberosity at the base of the fifth metatarsal bone. It is said to be rare; I have not observed

Fig. 4.—*Os Vesalianum Pedis*, represented by nonunion of the tuberosity of the fifth metatarsal.

in an adult foot. In the developing foot it is common, especially in the first two years of life, and is usually found in the first two years of life. It is usually found in the first two years of life, and is usually found in the first two years of life.

5. *The Os Intermetatarsale*.—This is a small, oval-shaped bone located between the first and second metatarsals. It is usually found in the first two years of life, and is usually found in the first two years of life.

(calcaneum) are great. Often the interosseous space between this process and the scaphoid and cuboid is quite wide and filled with cartilage. By calcification in this interosseous cartilage a secondary os calcis may arise. Such an extra bone may fuse with the projecting angle of the os calcis proper or with the scaphoid, or it may remain as a distinct extra bone (fig. 6). In two instances I have made the error of diagnosing such an anomaly as a fracture only to conclude after observing treatment over a period of weeks that the condition was not a fracture but an anomalous bone. The appearance of a freshly fractured process is usually distinctive (fig. 7).

6. *The Intermetatarsum*.—This is an extra bone located between the internal cuneiform and the first two metatarsal bones. It is said by Dwight to be present in 10 per cent of people,

but I have seen only one definite example and erroneously diagnosed that as fracture, changing the interpretation when I learned that there was no tenderness, pain or disability in that part of the foot.

7. *The Secondary Cuboid*.—This may occur as a separate fragment but is usually fused with the scaphoid at the lower and outer edge of that bone.

8. *The Subdivided Internal Cuneiform*.—This is mentioned by Dwight as a rare occurrence; I have never observed it.

9. *The Intercuneiform*.—This, another rare anomaly, is a wedge-shaped bone on the dorsum of the foot in front of the scaphoid.

10. *A Divided Sesamoid of the Great Toe*.—This anomaly is fairly frequent. When found in a patient who has dropped a heavy weight on the toe, it is difficult to convince surgeon, patient or oneself that it is an anomaly and not a fracture.

11. *A Separate Styloid Tip of the Fibula*.—This anomaly corresponds to that found in connection with the ulna and is occasionally observed. When found in connection with a sprained ankle, it requires good judgment on the part of the radiologist and considerable confidence in that judgment on the part of the surgeon to decide that the detached fragment was not torn off by the sprain. Sometimes the evidence is clear, at other times it is not.

12. *A Separate Styloid Tip of the Tibia*.—This is a small, pointed fragment of bone located at the lower end of the tibia, just above the ankle joint. It is usually found in the first two years of life, and is usually found in the first two years of life.

13. *The Os Intermetatarsale*.—This is a small, oval-shaped bone located between the first and second metatarsals. It is usually found in the first two years of life, and is usually found in the first two years of life.

Fig. 5.—Tibiale externum, represented by nonunion of the tuberosity of the third scaphoid.

correctly an appearance resulting from the presence of an accessory center of ossification.

Meyer and Forster,<sup>3</sup> describing a case in the Belgian literature, entertain the question as to whether there are not epiphyses normally appearing at the tips of the articular processes early in life. If this should be the case, failure of fusion might reasonably be expected to occur occasionally. Whether such epiphyses regularly occur in early life does not appear to be of great importance for, as pointed out by Mardersteig,<sup>4</sup> Reisner<sup>5</sup> and others, accessory centers of ossification occur with considerable frequency opposite the heads of the ribs and opposite the tips of the spinous processes as well as opposite the tips of the transverse processes. With such anomalous ununited epiphyses in mind it seems not illogical, especially in view of the frequent bilaterality of the anomalies at the tips of the inferior articular processes, also to consider them as ununited epiphyses. That these cases are merely accessory bones in the same class as the os trigonum, which appears so frequently opposite the dorsal lip of the astragalus, is the opinion expressed by Rendich and Westing,<sup>6</sup> who believe that

Fig. 4 (case 2).—Lateral view. The anomalous fissure shows clearly in this view.

because of this etiology the name accessory articular process (*processus accessorius articularis*) would be appropriate.

Of much more importance than the etiology of these anomalies is their differentiation from fracture. As with anomalous epiphyses anywhere else, the cortex is as well delineated opposite the opposing bony surface as it is in the periphery of the epiphysis. Not only is the delineation sharp but the fissure is usually well defined (in those cases in which there has not been partial fusion) and often it is to be found with a reasonable degree of symmetry on both sides. These facts were recognized by Nichols and Shiflett<sup>7</sup> and by Fulton and Kalbfleisch<sup>8</sup> as well as by the others who have already been quoted as having described cases of this anomaly. The importance of not making a diag-

nosis of "old fracture" unless there is a definite history of the type of injury described in the discussion on fractures has not been so generally appreciated, however. One author<sup>9</sup> is therefore found describing five cases of "isolated fractures of the articular processes of the lumbar vertebrae" in which the first case involves the tip of the superior right articular process of the

Fig. 5 (case 3).—A. M., aged 48, a physician, with no history of trauma, complained of urinary calculus. Anomalous fissure, right inferior articular process of the second lumbar vertebra.

third lumbar vertebra. The history of a twisting injury is definite, and the case seems definitely one of fracture. With the remaining cases the situation is somewhat different, however, for in three of them bilateral lesions were found and in none was there a history of trauma such as seems to be necessary to produce isolated fractures of the articular processes. There is also nothing about the radiographic appearance of these cases to differentiate them clearly from anomalies.

#### FRACTURES

Fractures of the articular processes in combination with severe injuries of the spine in which there is an actual dislocation of one vertebral body on another are not at all unusual. One or more articular processes are frequently sheared off under such circumstances.

Fig. 6 (case 4).—J. M., aged 28, a carpenter, with no history of trauma, complained that he had swallowed nails. Anomalous fissure at tip of right inferior articular process of third lumbar vertebra.

with regard to establishing the constancy or inconstancy of the epiphysis of the tuberosity of the fifth metatarsal. As Dr. Watkins showed, there is an area of density below the fifth metatarsal, near the tuberosity; in the study of these children we found that that epiphysis, in all probability—it is difficult to establish positively unless one follows children over a long period—is fairly constant. It is present, however, for such a short time during the life of the individual that the impression is gained that it is inconstant. A child of 11 may show the epiphysis; by the age of 12 frequently it has fused to the bone and cannot be seen. What I wanted to emphasize particularly was that a fracture occurring in that fashion certainly must be very rare. When fracture of the tuberosity of the fifth metatarsal occurs, it goes across in transverse fashion, and the disk-like shadow of the epiphysis should never be mistaken for it. My impression of the os vesalianum is that it is a very different structure; it is a little density proximal to rather than on the inferior outer surface of the tuberosity of the fifth metatarsal, and it is an extremely rare extra ossicle. Some years ago I studied a series of twins and triplets, and there was one set of identical triplets in all three of which the small ossicle of the internal malleolus of the tibia which Dr. Watkins demonstrated was present. Certain other anatomic variations occurred in some identical twins. Some of these variations are so unusual that it is reasonable to assume, in view of their presence in all three, that they are preformed, entirely genetic, and not due to changes in utero or later acquisition.

DR. WILBUR BAILEY, Los Angeles: Dr. Chandler brings up a significant point when he says that these anomalies may be points of lessened resistance and that after a trauma the question always arises whether the anomalous fissure may not have been a weakened point. We really do not have enough information as yet on this subject to be certain. There were six cases in which there was no history of immediate trauma, which if considered with the remaining four cases in which there was a definite history of trauma show no characteristics sufficiently marked to enable one to separate the traumatic from the nontraumatic cases.

DR. W. WARNER WATKINS, Phoenix, Ariz.: The title of my paper as published here, is misleading, as it says "bony anomalies." I confined myself to anomalous bones rather than to other anomalies and so did not try to include synostoses in the hand and wrist. I wanted to deal with those injuries that are mistaken for fractures. The paper came out of my experience with the Industrial Commission work. A plan has been adopted in Arizona which is rather unique; the referee of the Industrial Commission has been asking that all x-ray films made by practitioners all over the state, except the large corporations carrying their own insurance, shall be sent to his office. I have been called on for interpretations on doubtful injuries. Practically every anomaly shown here today came out of that experience and had been diagnosed fracture by some practitioner, not by a radiologist. In isolated districts the doctors have made their examinations and have done the best they could, but they made some very serious mistakes as far as the Industrial Commission was concerned. I am glad to know Dr. Rigler's explanation of the os vesalianum. I have never seen one and I am glad to know where it ought to be. I hoped to find it in making a review of all the hands and feet in my file but did not. I should like to express my appreciation of Dr. Bailey's paper, because in this work we have a medical rating board, of which I am consulting radiologist, and before this board the Industrial Commission every month brings its difficult cases. Out of 126 cases that we have had during the past year, seventy were supposed back injuries. In most of them I could not find the back injury. I shall review all the cases and see whether this particular lesion, which I confess I have not yet looked for, is present.

**No Syphilis in Gilbert Islands.**—Syphilis continues to be nonexistent, and only a few cases of gonorrhea are seen from time to time. The incidence of visible yaws in the Gilbert Islands is said to have declined markedly, secondary manifestations now being rarely met with; 10,073 anti-yaws injections were given at the various hospitals during the year.—*Trop. Dis. Bull.*, 33:214 (Oct.) 1936.

## CONGENITAL LUNG CYST

J. CASH KING, M.D.

AND

L. C. HARRIS JR., M.D.

MEMPHIS, TENN.

Congenital cyst of the lung may be defined as an intrapulmonary fluid sac of which the wall is composed of bronchial tissue and the fluid content is a product of the bronchial epithelium. Its formation is attributed to an anomalous occlusion of the bronchus in the embryo.

This condition, formerly seldom encountered, is now being recognized with increasing frequency with present day improved methods of roentgenologic technic. The literature is sufficiently complete to enable the well informed to make a diagnosis of cystic disease when the proper procedure of examination is followed. We believe that a larger number of cases would be discovered if routine roentgenograms of the chest were made on atypical pulmonary infections at the end as well as at the beginning of the disease. This statement is well supported by the cases cited by Kostlin,<sup>1</sup> Barlow,<sup>2</sup> Coats,<sup>3</sup> Frühwald,<sup>4</sup> Debré and Blinder<sup>5</sup> and many others. Further, after the early cases reported by Bartholinus<sup>6</sup> in 1687 and Meyer<sup>7</sup> in 1859, Koontz<sup>8</sup>

was able to collect only 108 from the world's literature to 1925, all of which were observed at autopsy, whereas 152 cases have been described in the past decade. We believe, therefore, that this pathologic entity should receive more thoughtful regard in the differential study of chest diseases.

Fig. 1 (case 1).—Roentgen appearance of chest, November 7, demonstrating fluid cyst as opacity in midportion of the right lung field.

The number of cases of cyst of the lung found at autopsy gives an inaccurate conception of its true incidence. The growth may be masked by secondary complications, such as abscess or rupture, and may be overlooked by the pathologist unless the bronchi are carefully searched for the site of obstruction. Also, those cases not diagnosed clinically which undergo spontaneous recovery never come to necropsy.

### REPORT OF CASES

The following case of expansile air cyst is the second recognized by one of us (King):

CASE 1.—D. S., a Negro girl, aged 8 months, was the only child of healthy parents. She was born after a normal labor and weighed 6 pounds (2,720 Gm.) at birth. Her infant cry and primary respirations had been spontaneous. There was nothing unusual in the child's progress until a few days before Nov. 5, 1935, when she was brought to the Memphis General Hospital. At that time a nasal discharge and a cough which

the articular process as do the anomalous ossicles. It is also to be noted in these cases that pain is prompt and severe, and impairment of function is lasting. It seems logical to believe that the occurrence of bony union will be dependent on blood supply as well as on treatment. If the fracture occurs near the tip of the process, the chances of union, as in the cases described, are not good. If the fracture is near the base, however, union will occur. This has been the experience in the cases I have seen in which more severe concomitant spine injuries were also present.

#### COMMENT ON CASES

Because of their similarity to cases 1 and 4 respectively, the roentgenograms in cases 9 and 10 are not shown. Their details were as follows:

CASE 9.—J. K., a man, aged 28, a laborer, complained of pain since straining his back while lifting. Anomalous fissures, bilateral, through the inferior articular processes of the third lumbar vertebra were found.

CASE 10.—A. B., a man, aged 35, a laborer, with no history of trauma, complained of indigestion. An anomalous fissure at the tip of the right inferior articular process of the third lumbar vertebra was found.

It is particularly instructive to note that in six of the ten cases which are presented the discovery of the artic-

ular process anomaly was incidental to an examination for some other purpose, and no history of significant trauma to the spine was elicited. If the anomaly cases with a history of trauma are compared with those giving no such history, no essential differences will be found.

The most usual locations of these anomalies are at the tips of the inferior articular processes of the second and third lumbar vertebrae, but in my experience all lumbar vertebrae have been involved. The fissures across the inferior articular processes of the fifth lumbar vertebra, however, were oblique and the impression from these cases was that the fissure appearance was due to an articular shelf in the transverse plane of the body, much as in the case of the cervical vertebrae, and that the tip of the articular process was not actually severed from its base. It seems entirely logical that anomalous ossicles should occur in the dorsal region; I have heard of one such case but none appear in the literature.

Although most of these anomalies appear in males, a few females are so affected. In the cases in which partial fusion has occurred, the fusion is always on the lateral side and the gap left on the mesial side has a smooth wedge shape which in no way suggests a fracture line. In some cases the only remaining evidence of these anomalous centers of ossification is to be found in the presence of a sharply defined notch in the mesial side of an inferior articular process.

In case 11, the history of a severe twisting injury to the spine due to a wagon wheel having passed over the

patient's back, as well as the finely serrated edges of the straight fissure which extends almost but not quite to the lateral edge of the inferior articular process, suggested the presence of the fracture. This belief was further substantiated when in the oblique view the fissure was seen to fork at its lateral end and thus to produce a tiny wedge-shaped fragment (fig. 12).

Fig. 11 (case 11).—J. A., aged 25, a laborer, gave a history of trauma capable of causing fracture. He complained of persistent pain after a wagon wheel ran over the middle of the back. There is a dark, straight fissure which extends almost to the lateral edge of the left inferior articular process of the second lumbar vertebra. The edges of this dark line show a fine serration which is not seen in the anomaly cases.

#### INCIDENCE

There are nineteen cases of these articular process anomalies reported in the literature, six of which are bilateral. Ten more cases are added in this study, two of which are bilateral. Most of the patients described in the literature are males; in most of them there has been a history of trauma, and all are in the inferior articular processes of the lumbar region. The exceptions to the last statement are a case reported by

Fig. 12 (case 11).—Left oblique view. The same inferior articular process is seen to have a dark line running across it. The line once again shows irregular edges and at the lateral aspect it forks so that a definite tiny triangular fragment is formed.

Litten,<sup>15</sup> in which a fissure was found across the right superior articular process of the third lumbar vertebra in a patient with a history of trauma after heavy lifting, and case 8 of this series, in which there was an anomalous fissure through the right superior articular process of the fourth lumbar vertebra with no antecedent history of trauma.

15. Litten, F.: Ueber Spalthildungen an den Gelenkfortsätzen der Wirbelsäule, *Röntgenpraxis* 4: 1039-1043 (Dec.) 1922.

Pearson,<sup>13</sup> in commenting on this case, diagnosed it as bilateral cystic disease. Apparently he failed to observe that the large cyst of the left lung herniated through the mediastinum into the right side of the chest while under intense pressure and that the entire sac returned to the left side of the chest when it collapsed.

#### ETIOLOGY AND PATHOGENESIS

It is almost unanimously agreed that cystic disease is congenital in origin. Many theories have been advanced to explain the anomaly, yet this academically important issue still is unsettled. Lohlein,<sup>14</sup> Buchmann,<sup>15</sup> Couvelaire,<sup>16</sup> Stoerk,<sup>17</sup> and Hüchel<sup>18</sup> observed epithelial and connective tissue proliferations and considered the lesion neoplastic in nature. Blatt and Jacobs<sup>9</sup> recently described similar changes. Heuter<sup>19</sup> and Grawitz<sup>20</sup> believed it to be a congenital bronchiectasis; Francke<sup>21</sup> and Heller<sup>22</sup> regarded it as a congenital atelectasis and de Lange<sup>23</sup> as an atelectatic bronchiectasis with defective development of the alveolar tissue and excessive dilatation of the bronchi. Virchow<sup>24</sup> and Klebs<sup>25</sup> considered it a lymph vessel dilatation. Sandoz<sup>26</sup> and Oudendal<sup>27</sup> were of the opinion that congenital syphilis

ing on these factors. In 1928 Mueller<sup>33</sup> published an excellent article giving a critical review of theories advanced prior to that time, to which the reader is referred.

Microscopic studies of the structure of a fluid cyst, as obtained from autopsy reports, reveal the following characteristics: The walls are formed of fibrous and elastic tissue and concentric muscle fibers with interspersed cartilaginous plaques. The lining of a small cyst possesses stratified ciliated columnar epithelium, which is flattened into cuboidal shape as the cyst increases in size. The albuminous fluid content is composed of mucus, cellular debris, desquamated epithelial cells and white blood cells.

In order to understand clearly the formation of a cyst in the lungs, it is necessary to analyze the lung development in the embryo. According to Simpkins,<sup>34</sup> the bronchi develop as small ramifications of solid entodermal tissue, which become canalized almost immediately. It is our opinion that an unknown process interferes with the canalization at some point proximal to the termination of that ramification, resulting in its occlusion and causing a portion of the radicle to persist

Fig. 4 (case 2).—Roentgen appearance after injection (through chest wall) of iodized oil: A and B are posterior anterior and lateral views; C, same case four and one-half years after complete recovery.

was an underlying cause. Box<sup>28</sup> and Bernstein<sup>29</sup> concluded that the process was a sequel of bronchopneumonia, possibly because of the frequently concurring pneumonitis. Parmalee and Apfelbach<sup>30</sup> advanced the idea that the cysts originate as small bronchiectatic cavities, which become distended with fluid during prenatal growth. Miller<sup>31</sup> and Wood<sup>32</sup> are of the opinion that there may be many unknown factors which are instrumental in the production of congenital cysts of the lung and believe that the subsequent progress has little bear-

as a mass of cells. Canalization begins again distal to the occlusion, producing an isolated canalized segment with normal mucous membrane, which assumes its natural secretory function. This secretion accumulates and, since it has no exit, forms a cyst (fig. 5). Lung cysts with wall structure characteristic of bronchial tissue have been found at autopsy performed on infants who died at birth, as reported by Wolman,<sup>35</sup> Pappenheimer,<sup>36</sup> Kessler,<sup>37</sup> Smith,<sup>38</sup> Collins<sup>39</sup> and others. In some of these the cysts formed prior to the development of alveolar tissue. Necropsies of those patients who lived for a time failed to reveal pigment in the cystic area, although it was present in the remaining lung tissue. These facts seem to establish the congenital bronchogenic origin of the cysts.

Probably the rapidity of prenatal growth and the size of the cyst at birth are dependent on (1) the amount of functioning bronchial mucosa entrapped and (2) the capsular strength of the cyst.

Postnatal growth usually is more rapid, being encouraged by the negative intrathoracic pressure, which

3. A secondary pisiform bone may exist, seen more distal in the carpus than the os triangulare.

4. Still more rare is the ulnare externum, a separate fragment associated with the cuneiform (triquetral) bone.

5. The os centrale more often persists as cartilage, even in the fully developed wrist (fig. 1). In such cases it is seen as an area of absent density in the radial side of the os magnum. When ossified, it may be joined to the scaphoid or more rarely may exist as a separate ossicle (fig. 3).

6. The radiale externum is a separate bone fragment found just distal to the styloid process of the radius. It is not associated with the radius but is an unfused tubercle of the scaphoid (navicular) bone.

7. The epilunatum is the dorsal tip of the semilunar (lunate) bone, which occasionally exists as a separate fragment.

Fig. 1.—Divided scaphoid (navicular). The division apparently is not complete, the two fragments being united by a thin bridge of bone. There is no history of injury. A cartilaginous os centrale is also shown, represented by the notch in the radial side of the os magnum (capitate).

Fig. 2.—A distinct separate bone distal to the styloid process of the ulna. This is more likely a small sesamoid than an ununited styloid tip.

Fig. 3.—An os centrale associated with the scaphoid bone, but showing as a distinct ossicle.

8. The pretrapezium is the distal end of the ridge of the trapezium (multangular majus), which may occasionally exist as a separate fragment.

9. The subcapitatum is the distal end of the os magnum (capitate) on the palmar surface, which has been found as a separate fragment.

10. The secondary trapezoid is a free bone found in almost the same position as the pretrapezium but arising from the base of the second metacarpal bone.

11. The styloid process of the second metacarpal bone may develop independently and remain free or become fused with the trapezoid (multangular minus) or os magnum (capitate).

12. The os vesalianum manus is a free bone situated at the base of the fifth metacarpal. The tubercle for the attachment of the extensor carpi ulnaris varies considerably in size, and a fragment of it may exist as a separate ossicle. I have never encountered this anomaly, but I can easily see how it would offer difficulties and that it would probably be diagnosed as a sprain-fracture involving the attachment of the muscle mentioned.

#### FOOT

In the foot and ankle region there are twelve anomalous bones which need to be recognized.

1. *The Os Trigonum.*—The posterior projecting portion of the astragalus (talus) is grooved for the tendon of the flexor hallucis longus. External to this groove is a prominent tubercle, the posterior process, to which the talofibular ligament is attached. This process varies greatly in size and shape; it is often observed developing as a separate epiphysis in the growing individual, and various degrees of fusion are found in the adult. In about 10 per cent of cases this process or tubercle is found as a separate or incompletely fused bone (fig. 4). There seems to be some disagreement among anatomists as to whether such a separate bone, when present, is an unfused posterior process or a distinct bone lateral to the posterior process. Pfitzner, probably the greatest authority on skeletal variations, contends

that it is a distinct bone. When such a detached fragment is shown in a roentgenogram of the foot, taken after an injury, the question of its status immediately becomes important. Decision must be made as to whether it is an anatomic variation and of no clinical importance or whether it is a fractured posterior process probably associated with rupture of the talofibular ligament. Sometimes the x-ray evidence is clear cut that it is either a congenital nonunion or a fragment detached at a time so remote that definite structural changes have developed. Usually the question of traumatic detachment must be answered by the x-ray evidence and observation, by a series of films suitably spaced.

2. *The Tibiale Externum.*—Two structures are called by this name. One is a sesamoid in the tendon of the tibialis posticus; the other is the unfused tuberosity of the scaphoid (navicular) bone (fig. 5). Both of these are seen frequently. The sesamoid bone is usually separated sufficiently from the scaphoid so that the question of fracture is not raised. However, the ununited epiphyseal tuberosity, or true tibiale externum, is often quite confusing. Since the tendon of the

early months of life and is first brought for examination because of an attack that was not unlike the previous ones until the child became dyspneic and cyanotic. The dyspnea, as a rule, is persistent, but the cyanosis is characterized by periods of remission. The child may recover spontaneously or may die during one of the attacks, as did one of the patients in this series. Large expansile cysts present this picture. Prior to the onset of cyanosis and dyspnea, one frequently obtains the history of a cough productive of a tenacious mucilaginous substance. The appearance of the fluid indicates the beginning of bronchial communication. Expectoration of blood-tinged pulmonary secretions, occasionally observed, is explained by rupture of the small adjacent vessels when coughing efforts increase the pericystic pressure. It should be remembered, however, that a cough is not always a symptom.

These patients are acutely ill at some stage of the disease. They appear lethargic, have anorexia, suffer

Fig. 5.—Diagrammatic illustration of embryonic ramifications of the bronchial tree: A, interrupted canalization of a ramification; B, canalization starts again distal to occlusion; C, fluid cyst formation.

with nausea and vomiting, either lose weight or fail to gain, and often show evidence of dehydration. These, however, cannot be labeled as prominent manifestations. The most one can say about the symptoms of cystic disease of the lung in children is that they coincide with those of pulmonary infection until the time the air chamber forms.

#### DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS

In our review of the literature we were able to find only one instance in which a clinical diagnosis of uncomplicated lung cyst was made prior to roentgenologic examination, which demonstrates the significance of the rôle of roentgenology in the diagnosis. This is not surprising, since there is so little in the symptomatology and nothing in the physical changes pathognomonic of the disease. It is obvious, however, that the importance of the clinical record is becoming more apparent with the accumulation of reported cases.

A careful roentgenologic study includes examination with the fluoroscope in all positions, as well as films made in vertical, horizontal and lateral positions. One finds single or multiple, sharply defined intrapulmonary shadows having the density of either fluid or air, or both, with a fluid line.

Cystic disease of the lung should be suspected in infants and children who suffer repeated attacks of respiratory infections in which dyspnea and cyanosis are unduly prominent. The suspicion should be stronger when these appear immediately after the child has coughed or expectorated a quantity of albuminous fluid.

Small fluid cysts, per se, seldom produce physical signs. When large and located peripherally, regional dullness and diminished vocal and breath sounds are elicited but are subject to variation in the presence of secondary infection.

Balloon cysts produce the physical appearance of pneumothorax under pressure; i. e., bulging thoracic cage, limitation of motion, tympany on percussion, absent breath sounds, and contralateral displacement of the mediastinum and diaphragm. In the roentgenogram, the entire lung field may be replaced, and the normal convex mediastinal and diaphragmatic contours compressed into concave lines.

The diagnosis of balloon cysts should present little or no difficulty from the history and physical and roentgenologic examinations, but the dense intrapulmonary ovoid shadow of fluid cysts must be differentiated from pulmonary consolidation, atelectasis, interlobar sacculations of fluid, pleural empyema, pulmonary abscess, solid tumors, and cysts of the echinococcal and dermoid varieties.

Of the many perplexing problems offered in differential diagnosis, the one that we wish to stress is the distinction between fluid cysts and pneumonic processes. As previously pointed out, one is confronted with the clinical picture of pneumonia. Unfortunately, this diagnosis often is confirmed by the roentgenologist, who demonstrates a curvilinear density in the pulmonary field. Since the concurring pneumonitis frequently responds in a short time to the usual treatment, one is further deceived as to the original disease process. The child is pronounced cured, when another roentgenogram of the chest would show the persistence of the cystic opacity and give a clue to the diagnosis. This explains why the diagnosis is not made until rupture occurs, even though the history obtained relates repeated cycles of the course described.

Atelectasis, as a rule caused by a foreign body in a portion of the bronchial tree, can be distinguished in the majority of cases by the history, by bronchoscopy, and by the clinical progress.

We have observed interlobar sacculations of fluid which presented a clinical picture identical to that of fluid cysts, as well as similar intrapulmonary densities in the roentgenogram. Lateral views, however, illustrated the line of thickened interlobar pleura leading to the fluid accumulation, establishing its identity.

A secondarily infected cyst, or one with extensive surrounding infection, simulates lung abscess and localized empyema. Wood<sup>22</sup> emphasized the point that abscesses either regress or progress, and the change may be observed roentgenologically. Eloesser<sup>23</sup> directed attention to the wedge-shaped shadow of localized empyema as compared with the ovoid shadow of cysts. Bronchoscopic examination and visualization of the bronchial tree with iodized oil may be necessary. More often than not, exploratory thoracotomy is required for differentiation.

From solid tumors, which are more dense, more sharply defined and develop later in life, cysts may be distinguished by aspiration or at operation. Echino-

genologist in studying and treating injuries to the joints of the extremities. Only the most scrupulous care in making and interpreting roentgenograms, coupled with good critical judgment by the surgeon, both based on exact anatomic and physiologic knowledge, will prevent injustice to the patient and costly errors in diagnosis.

### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BAILEY AND WATKINS

DR. ARTHUR STEINDLER, Iowa City: Accessory centers of the vertebrae are known to be present regularly at the tips of the transverse and the spinous processes. Less is known of the secondary centers of ossification over the tips of the articular processes. It was a good point to bring in the so-called absorption zones of Loeser because of the fact that these absorptive zones are observed and considered of importance in those cases of separation which occur between the upper and lower articular processes, that is, in the so-called isthmus, where they are supposed to be responsible for spondylolysis and the development of a separate neural arch. I have observed four cases of fracture of the articular processes of the lumbar spine. The fractures were caused three times by direct violence and once by indirect violence. In two cases the lower articular process was fractured and in two cases the upper articular of the fifth lumbar was fractured. They were all associated with back injuries, especially sacro-iliac injuries. The roentgenogram showed what was considered to be healed fractures of the lower articular processes of the lumbar spine. All these articular processes demonstrated here were directed in the sagittal plane. The greatest encroachment in the mobility of the lumbar spine, with the exception of the sacral lumbar juncture, is the rotation. I believe that when the force strikes the vertebrae it is not so much the lateral deviation as the rotation by which a locking of the articular processes occurs and brings about the fractures seen in the demonstration of Dr. Bailey. I have occasionally seen divided scaphoids. One has to decide from the smoothness of the joint surface and the density of the two portions of the bone that the condition is an anomaly and not a fracture. Cystic degeneration often accompanies fractures and is significant of traumatic origin. Congenital synostoses occur between the carpal or tarsal bones.

Fig. 6.—The secondary os calcis, due either to nonfusion of the anterior process of the os calcis or to calcification in the interosseous cartilage. This was diagnosed as a fracture at first.

I have observed a woman with fusion of the first three and the last two metacarpals, and exostosis between the metatarsals and six toes, who had a congenital synostosis between the hamate and the capitate. As to the etiology, one can only speculate. With regard to synostosis of the tarsus, however, one is probably getting a better idea of how the condition comes about. The condition has been known since 1880. Slomann has made quite a study of the calcaneoscaphoid synostosis, which I have observed in two cases. It is probably due to the ossifica-

tion of the os calcis with the os calcis secundarium, which, according to Pfitzner, occurs in 1 per cent of the cases. Six such cases were reported by Bentzon. I have observed two.

DR. FREMONT A. CHANDLER, Chicago: The ossification of the posterior element of the spine progresses from a center at the base of the transverse process posteriorly. One therefore must look for the interruption of the ossification rather than the formation of an extra center to account for the lesions

Fig. 7.—True fracture of the anterior process of the os calcis

demonstrated by Dr. Bailey. Similar defects of ossification may be seen in the total absence of the articular process or the great variety of anomalous shapes which this process may have. The clinical recognition of such a lesion is undoubtedly of the greatest importance, and it is significant that the illustrations shown by Dr. Bailey were taken from patients presenting no local complaints. Whether or not an injury produces such a transverse lesion or whether it aggravates it introduces a most important question regarding the compensability of such a lesion. In most states, aggravation of a preexisting condition is recognized, and I believe that in these lower articular process lesions this state of affairs exists. Occasionally loose ossicles may be encountered during the course of a spine fusion operation. The most significant point of differentiating a congenital defect from a fracture at this site would be the alteration of the bone substance over a period of time, as reflected in the x-ray films. If due to fracture, progressive absorption and eventual recalcification would probably occur. In one or two of the illustrations shown by Dr. Bailey there was evidence of spur formation at the margins of the vertebral body. To me the occurrence of such spurs would indicate that trauma, acute or chronic, may have some direct relationship to the separate center of ossification. Dr. Watkins has given a thorough review of the major works dealing with the bony anomalies of the hand and foot. An orthopedic surgeon is interested in these anomalies as a means of differentiating fractures as well as explaining local symptoms. In the foot, the os tibiale externum is probably the most important. It is seen frequently in pronated feet and presents the clinical and pathologic picture similar to that found in Osgood-Schlatter's disease. Next in importance is the bipartite sesamoid, usually found in relationship to the head of the first metatarsal. These may be bilateral and have no clinical significance. They do, however, give a poor weight-bearing surface, which is susceptible to direct or indirect strain. Excision of such a divided sesamoid must be done with the greatest caution so as not to disturb the action of the short flexor tendon of the first toe. Third in importance is the separate center of ossification at the proximal end of the fifth metatarsal bone. This may be confused with fracture.

DR. LEO G. RIGLER, Minneapolis: I want to comment on the paper of Dr. Watkins and report two pieces of unpublished work that might be of interest. One of my assistants, Dr. John Eneboe, and I, some years ago studied several hundred children

observation, with prophylaxis against infection, should be carried out in these patients until they reach an age when procedures in thoracic surgery may replace the less efficacious palliative efforts to cure a condition of grave prognosis.

860 Madison Avenue.

#### ABSTRACT OF DISCUSSION

DR. L. R. SANTE, St. Louis: We have all been guilty in the past of calling certain shadows, especially along the side of the mediastinum, localized pleural effusions when they really were cysts of the lung. Whether it is lined with a secreting membrane or not it is impossible to tell in the roentgenogram. Due consideration of the clinical symptoms will aid in the differentiation. The fullest consideration of the clinical history and the subsequent developments of the case is always essential for the differentiation of this condition. If there is associated infection of the cystic area, it may be impossible from the roentgenogram alone to make a differential diagnosis. If, however, there are relatively few symptoms and signs and the case is observed over a considerable time under varying conditions of distention of the cyst with fluid, the diagnosis at least becomes presumptive. The absolute proof is dependent on conditions found at the autopsy. The expansile air cyst of the lung gives an entirely different picture. This type has been most frequently encountered in the very young. One must not get the wrong impression about the formation of balloon cysts of the lung as to how much they inflate and as to the mechanism by which inflation takes place. A check valve may give the impression that with every respiration the balloon cyst gets larger and larger until it ruptures. This can hardly be the case mechanically, because air enters the lung at all only by reason of the enlargement of the thoracic cage, and the amount of distention is dependent on its enlargement as exerted against the counter force of the elasticity of the lung, so that in the case of a cyst the thickness of the wall and its elasticity seem to be the determining factors as to how large it will get as the result of inspiration. After it has attained that size, and after that pressure has been equalized, it never gets any larger by subsequent respiration. It does have the effect of increasing the pressure in this area, however, so as to inhibit subsequent secretion from the living membrane, and perhaps that is the reason it remains an air cyst. Injection of iodized oil in a certain type of cases gives the typical appearance of bronchiectasis. I believe these represent multiple cystic areas, intimately connected with the bronchi, which leave, as is evident, free ingress and egress of air and yet actually maintain themselves as cystic areas in the lung.

DR. JAMES L. DUBROW, Des Moines, Iowa: I saw a patient hospitalized for five months in the orthopedic ward, who developed a sudden dyspnea although there was no history of any previous pulmonary or heart disease. Based on the physical examination and the bedside chest film he undoubtedly had spontaneous pneumothorax. He seemed fairly comfortable but died a few hours later in spite of treatment. Autopsy showed displacement of the heart and the mediastinum to the right side with much air in the left pleural cavity. The collapsed left lung showed numerous air cysts, the right lung also showing a few. I cannot state whether these cysts are congenital, not having as yet conclusive histopathologic data on the case.

DR. CARLETON B. PEIRCE, Ann Arbor, Mich.: I feel that, considering the rapidity with which the lung will excavate in a certain area following a lobular pneumonia or bronchopneumonia and develop cysts or a cyst in that area, the production of such a cystic area is entirely too common to permit one to call a great many of these "congenital cysts." Furthermore there is usually not much information about these youngsters until a certain age period. It seems to me that we must be extremely cautious in calling these congenital cysts. I am inclined to believe that most of the pneumocysts are acquired.

DR. LEO G. RIGLER, Minneapolis: I reported a case in which I was able to observe this phenomenon of destruction, mentioned by Dr. Peirce, occurring in staphylococcal pneumonia, which eventually produced a typical picture of a lung cyst in an adult. There is no doubt that this type of check valve obstruction of the bronchus may occur: with a previous excavation of the

lung from some inflammatory process a cavity may remain, and what is exactly similar to a cyst may remain and continue to fill with air because of the change in the bronchus. It takes a good deal of evidence to demonstrate clearly that these are not acquired.

DR. J. CASH KING, Memphis, Tenn.: One reason for making this presentation was the fact that we had discovered this one case in which we were able to study the fluid cyst in a young child and then to see it pass on into the expansile stage. I agree that there are many cases of apparently acquired lung cyst. We refer to them as emphysematous air sacs and we have seen them form within a short period of time and disappear in an equally short period. They were caused by the check valve type of occlusion, the result of a pathologic condition. Fluid cysts exist in many cases at birth, and they have been found in embryos to form prior to the time alveolar tissue develops. And in those patients who have lived they do not show pigmentation within the cystic area, even though this is present in the remaining lung tissue, which shows that they must be present. We have had some discussion with reference to the possibility of these lung cysts collapsing. Many authors have not seen a case in which the cyst has collapsed, and from the appearance of the autopsy specimens of the cases that have been present for a long time it would seem as though it would be impossible for that cyst cavity to collapse. In infants, however, it does not exist over too long a period, as shown in the second case reported. These cystic cavities will collapse completely and leave little or no evidence of their presence. We did not attempt to discuss the treatment but I want to emphasize the idea that treatment of fluid cysts encountered in small infants should be prophylactic, infection being warded off in every way possible. If necessary, more radical measures may be used to eradicate the cyst at a later period.

#### THE RELATIVE IN VITRO ACTIVITY OF CERTAIN ANTISEPTICS IN AQUEOUS SOLUTION

ROBERT N. NYE, M.D.

BOSTON

In the past ten years, innumerable articles concerning antiseptics have been published. Hardly a year passes without the appearance of a new proprietary bactericide. In advertisements in medical journals, magazines and newspapers and even in programs over the air the marvelous germ-killing properties of this or that antiseptic are brought to one's attention. Less credulous physicians are puzzled as to the solution of choice, whereas the more credulous are easily influenced by the astonishing claims of the manufacturers of certain solutions. One only needs consult the pharmacist of a large general hospital to learn of the many kinds of antiseptic solutions that are demanded by different staff physicians.

The experiments subsequently described were undertaken in an effort to determine the relative in vitro activity of certain proprietary and nonproprietary solutions which are ordinarily used as antiseptics for minor wounds and for irrigations. It is hoped that the accumulated data will serve to point out the discrepancies between the claims for certain proprietary solutions and the experimental facts and will enable the practicing physician to use and to recommend the use of antiseptics more advisedly.

What are the prerequisites of a solution of this sort? Although bactericidal action, as determined in the usual way, is of primary importance in evaluating the value of any antiseptic, this property alone is of

From the Mallory Institute of Pathology, Boston City Hospital.

produced mucoid material had developed, and she began tugging at her ears. Two days prior to admission she had become dyspneic and febrile.

On physical examination she was well developed and well nourished. Her temperature was 103 F., and respirations were 46 per minute. She had an occasional cough, a mucoid nasal discharge, pharyngeal hyperemia and a catarrhal injection of both tympani. Scattered râles were heard throughout both lungs.

Laboratory studies revealed white blood cells 28,000, red blood cells 4,300,000, hemoglobin 13.2 Gm. per hundred cubic centimeters, polymorphonuclear neutrophils 71 per cent, polymorphonuclear eosinophils 2 per cent, lymphocytes 21 per cent, myelocytes 4 per cent, and large mononuclears 2 per cent. The results of urine analysis and other laboratory tests were insignificant.

Examination of the patient's chest two days after admission elicited signs of consolidation in the midportion on the right. The temperature was now further elevated and showed a septic curve. Bilateral myringotomy induced the drainage of frank pus. Roentgenograms of the chest at this time demonstrated a well circumscribed curvilinear area of opacity measuring 1 by 1½ inches in the upper part of the lower lobe of the right lung (fig. 1). Following myringotomy and routine treatment, the child improved to some extent. The clinical course, however, continued to indicate a septic condition, and on November 23, eighteen days after entering the hospital, she became lethargic, her respiratory rate increased, and her cough ceased to be productive. November 27 it was noted that evidences of consolidation had disappeared over the right side of the chest and breathing on both sides had become wheezy. Two days later a bilateral mastoidectomy was performed. The temperature rose to 106 F., coincident with the appearance of the signs of meningismus. The râles were more diffuse and the percussion note over the lower right side of the chest was hyperresonant. For the first time cyanosis was apparent. Although these symptoms were fairly continuous, there were exaggerated periods in which death seemed inevitable. The child vomited frequently, refused food and showed evidences of early dehydration.

It was not until December 7 that a second roentgenogram disclosed a multilocular air sac replacing not only the area of cloudiness seen at the previous examination but also the lung tissue of the middle and lower lobes of the right side of the chest. The diaphragm was displaced downward and the heart to the left (fig. 2). The pressure within the cystic sac increased during inspiration. A differential roentgenologic survey resulted in a diagnosis of lung cyst.

Fig. 2 (case 1).—Second examination, December 7, apparently fourteen days after bronchial communication. Anteroposterior and lateral views showing replacement of fluid cyst by large expansile air cyst.

The clinical course continued as before until December 11, about five weeks after the patient's admission, when the intensity of the paroxysm of cyanosis, dyspnea and lethargy failed to subside, and she died.

The case presented is that of a multilocular solitary cyst involving a portion of the right lung. The picture, as visualized through the history, the physical and roentgenologic observations and the clinical course, illustrates, first, a classic expansile fluid cyst colored by secondary infection, and, secondly, the usual fatal termination of congenital cystic disease following the

establishment of a certain type of bronchial communication.

The child enjoyed a normal existence, carrying a lung cyst from birth with impunity, until subjected to a severe infection of the upper respiratory tract. During a seizure of vigorous coughing the fluid cyst ruptured into an adjoining bronchiole, causing the expectoration of its albuminous contents. The bronchial aperture thus formed acted as a one-way valve mechanism. After allowing the exit of the cystic fluid, air entered and the valve closed the opening, preventing its egress. With each respiratory cycle the cystic cavity was further distended. When roentgenograms were subsequently made, no retained fluid was observed; air occupied the entire cavity, which was greatly enlarged and had extremely thin walls. The air was under pressure, thus displacing the mediastinum and depressing the diaphragm on the right. The decreasing pulmonary field caused progressive dyspnea, cyanosis and eventual death. Although autopsy was refused, we feel justified in labeling the condition a congenital cyst. Similar cases have been found by Blatt and Jacobs,<sup>9</sup> Hünemann and Sievers,<sup>10</sup> Fontanus<sup>11</sup> and others.

Following is a follow-up report on a patient with congenital air cyst of the lung who has now been well for four and one-half years. The case was reported in THE JOURNAL in 1933 by Dr. Clyde Croswell and one of the authors.<sup>12</sup>

CASE 2.—N. D., a white boy, born without incident to normal parents, showed no signs of an abnormality until he was 5 months of age. At that time he had an acute illness which was diagnosed as bronchopneumonia, from which he recovered under the usual treatment. At 12 months of age he had a recurrence of the illness and for three consecutive months suffered a similar attack, with a similar recovery from the first two. The third, however, was complicated by otitis media, and it was also noted that the child expectorated a large quantity of yellow material on several occasions. When the fever subsided in the last paroxysm he continued to suffer from progressive dyspnea. The physical and roentgen manifestations were those of expansile air (balloon) cyst of the lung (fig. 3).

The child was kept alive for thirteen weeks by repeated thoracenteses, neutralizing the intrathoracic pressure. A spontaneous recovery was observed seven days after the injection of iodized oil into the cystic cavity (fig. 4). He has continued to be well and has developed normally. A recent examination revealed a small amount of the iodized oil in the left side of the chest but no other residual evidence of the original cyst.

It is our belief that cure resulted from occlusion of the bronchial communication and destruction of the bronchial mucosa lining the cyst and that the iodized oil and infection brought about this change.

Fig. 3 (case 2).—Posterior anterior view of very large air (balloon) cyst, originating in the left apex, herniating through mediastinum, compressing the upper half of the right lung and the entire left lung.

coccus aureus of standard resistance to 5 cc. of increasing dilutions of each antiseptic. After incubating in a water bath at 37 C. for exactly five minutes, one 4 mm. platinum loopful is transferred to 10 cc. of beef extract broth, prepared with a special batch of peptone (Armour's). After completion of these transfers, four 4 mm. loopfuls are transferred from the first tube to a second tube of broth. The latter is a modification suggested by Shippen<sup>2</sup> to eliminate the bacteriostatic effects of many of the mercury compounds. All tubes are incubated at 37 C. for forty-eight hours. The effective killing dilution is the highest dilution from which transfers failed to grow in both tubes.

fluid of a twenty-four hour culture of *Staphylococcus aureus*, which had been slowly centrifugated for five minutes. This amount of culture was approximately seven times the minimum amount of the culture that would grow in control broth tubes. As will be seen from table 1, none of the solutions showed bacteriostatic effects except those of the mercury group. All but one of the latter were bacteriostatic, but the effect was less marked than that shown by the first transfers. This was most probably due to the combination of the effective traces of mercury in the higher dilutions with the protein substances in the broth during the primary incubation period.

Numerator = result of first transfer; denominator = result of second transfer; 0 = no growth; + = growth; boldface type = highest bactericidal dilution; exponential sign = result of reinoculation of first transfer.

The results are shown in table 1. Compound solution of iodine, U. S. P., was by far the most effective. The bactericidal activity of the other solutions containing iodine was directly proportional to their iodine content. In all an actual iodine concentration of about 1:4,500 killed the cocci. Solutions containing chlorine came next in effectiveness, then the miscellaneous group and finally the mercury compounds. The last group showed considerable bacteriostatic power, but actual killing was accomplished by only three, of which one had to be used undiluted and another diluted only 1:2.

To recheck on bacteriostatic effects, all first transfers failing to grow in forty-eight hours were reinoculated with one drop of a  $10^{-4}$  dilution of the supernatant

#### BACTERICIDAL ACTIVITY IN MIXTURES CONTAINING FIFTY PER CENT HORSE SERUM

Each antiseptic was mixed with an equal amount of horse serum, which had been sterilized by passage through a Berkefeld filter. This mixture was allowed to stand at room temperature (about 22 C.) for approximately sixty minutes. Dilutions were then made with sterile 0.85 per cent salt solution and their bactericidal activities were determined by using the same method as in the previous tests.

The results are shown in table 2. As the antiseptics were diluted 1:2 with the horse serum, this is obviously the lowest dilution that could be tested. The three strongest iodine solutions were the only ones that retained bacteria-killing power in the presence of serum. The activity of the strongest as compared with its activity in the absence of serum was unaffected,

2. Shippen, L. P.: A Fallacy in the Standard Methods of Examining Disinfectants. *Am. J. Pub. Health* 18:1231 (Oct.) 1928.

begins with respiration. Growth of the cyst compresses the surrounding bronchi, causing atelectasis distal to the compression and thus encouraging infection in the bacteria-laden lung tissue. The course of the cyst may be altered by these changes, or its presence may be entirely obscured. Infection likewise plays an important part in the rupture and evacuation of the cystic fluid. However, Ribadeau-Dumas and Rault,<sup>40</sup> Cautley,<sup>41</sup> Wood<sup>32</sup> and others report necropsies in which no inflammation was apparent.

Grossly, the subsequent behavior of a lung cyst may take one of two courses: First, it may rupture into a bronchus or, second, it may remain a fluid sac without bronchial communication. A study of these actions constitutes the most interesting and instructive phase of cystic disease, since it is from this point forward that the varied clinical pictures develop. For simplification of this study, we submit the diagram shown in figure 6.

From a survey of the literature, the termination most frequently observed is rupture into a bronchus. This establishes different degrees of bronchial obstruction, on which the clinical manifestations depend.

Chevalier Jackson<sup>42</sup> described the types of bronchial obstruction and correlated their mechanics and physical signs. He stated that these obstructions are represented in mechanics by (1) a stop valve, (2) a check valve and (3) a bypass valve.

The obstruction that is commonly accepted for an explanation of the expansile balloon cyst formation is Jackson's check valve type (fig. 6). This valve-like action occurs when a bronchial connection is established which permits the ingress of air without corresponding egress. The autopsy records of Nelson<sup>43</sup> and Jacobs<sup>44</sup> clearly demonstrate this mechanism, and the two cases that we describe were, at one stage, also examples.

In another type, the ruptured opening is small but sufficiently large to allow both ingress and egress of air, forming a bypass valve and resulting in a nonexpansile air cyst. Hünemann and Sievers,<sup>10</sup> Miller<sup>31</sup> and Hennel<sup>45</sup> have reported cases belonging to this group. A number have likewise come under our observation.

When the opening is large and free, unobstructed bronchial communication is established and the cyst is cured spontaneously. Zarfl,<sup>46</sup> Vollmer<sup>47</sup> and Schenck and Stein<sup>48</sup> describe cases in point. This form of termination occurs more often than one is aware of and may be a factor in the low incidence reported at necropsy.

All fluid cysts of the lung are caused by Jackson's so-called stop-valve occlusion. When the wall of the cyst is sufficiently strong to support an intracystic pressure which inhibits the secretory activity of the mucous cells of the germinative lining membrane, the fluid cyst remains as an asymptomatic parasite, as illustrated by Wood,<sup>32</sup> Basso<sup>49</sup> and Paviott.<sup>50</sup> This type is important from a standpoint of differential diagnosis, since usually it is discovered by accident. Kleine<sup>51</sup> and Mencarelli<sup>52</sup>

have each reported a case in which an unruptured asymptomatic cyst aborted through the visceral pleura, remaining attached by a pedicle.

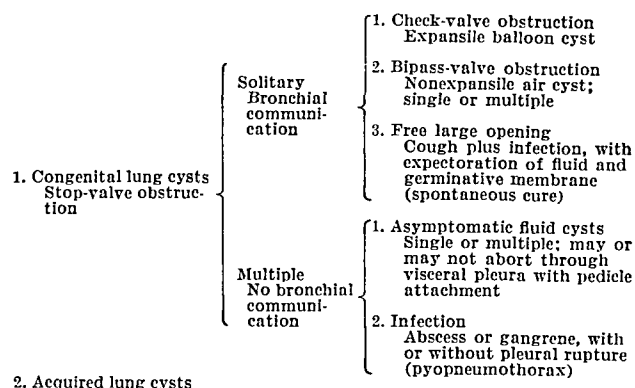

Infection of a cyst may occur by extension of bacteria through its walls, causing isolated abscesses. This was true of three cases cited by Sergent and his co-workers<sup>53</sup> and was further substantiated by the work and case reports of Zdansky,<sup>54</sup> Siems<sup>55</sup> and Pollock and Marvin,<sup>56</sup> who recovered pure cultures of Pfeiffer's bacilli from lung cysts.

If the cyst ruptures into the pleural cavity, a hydrothorax results; or, if infected, a pyothorax results. If pneumatized tissue is encountered in rupture, air will be present above the fluid line.

#### CLASSIFICATION

Cystic disease of the lung may be divided into two main varieties, (1) congenital and (2) acquired, either of which may be solitary or multiple. Anspach and Wolman<sup>57</sup> and Dubrow<sup>58</sup> have offered classifications according to the pathogenesis. We have delayed making a classification because we note that there is little difference between solitary and multiple cysts so far

#### Classification of Lung Cysts

as their etiologic or pathologic manifestations are concerned. It is our opinion that any classification of cystic disease of the lung which goes beyond the division of congenital and acquired constitutes merely an enumeration of the different pathologic states that may develop in the progress of the growth. The diagrammatic illustration presented in figure 6 is derived from a study of our cases and a review of the literature as well.

#### SYMPTOMATOLOGY

Unfortunately, there is no symptom or train of symptoms pathognomonic of lung cysts. Many congenital cysts without secondary infection are symptom free and may not be recognized at all, as in the cases of Miller,<sup>31</sup> Wood<sup>32</sup> and Pollock and Marvin.<sup>56</sup> The symptoms that usually bring the disease to mind are related to the infection present and to the changes produced in intrathoracic pressure following rupture into a bronchus.

According to the usual history, the patient has had recurring attacks of respiratory infections since the

amount of sterile 0.85 per cent salt solution for exactly five minutes. To promote more efficient diffusion, the sac was partially and rapidly removed and immersed ten times at two minutes, four minutes and four and one-half minutes after the start of the dialysis. The fluid levels inside and outside the sac were approximately equal. The dialysate was tested for bactericidal activity by the "F. D. A. (special) *S. aureus*, 37 C." method, except that dilutions were made with sterile salt solution rather than with sterile water.

The results are given in table 4. Only five of the dialysates were bactericidal. The three strongest iodine solutions had diffusion rates of 12.5 per cent. One

and resuspending in 5 cc. sterile Locke's solution. The cocci were killed by heating for six hours at 53 C. The tubes were then slowly rocked in an incubator room at 37 C. for twenty minutes. Smears were made on slides and these were stained with Wright's stain. The slides were examined microscopically and the number of neutrophilic polymorphonuclear leukocytes judged to be dead or badly injured at the time the bacteria were added was determined. Cells containing no cocci or only two or three were considered functionally inactive. Those containing moderate numbers of cocci were also noted, as these seemed to be cells that were active at the time the suspension was added but were subse-

of the mercury solutions had a rate of 25 per cent, which was not surprising in view of the fact that it was a solution of an inorganic salt which was probably highly ionized because of the presence of a small percentage of hydrochloric acid. One of the chlorine solutions showed 6.25 per cent diffusion.

TOXICITY

Mixtures of 0.25 cc. each of freshly defibrinated human blood and of different dilutions of the antiseptic solutions, prepared with Locke's solution as a diluent, were incubated in a water bath at 37 C. for exactly ten minutes. Then to each was added one drop of a heavy suspension of killed *Staphylococcus aureus*. This suspension was prepared by washing down with sterile 0.85 per cent salt solution the growth from two large agar slants (in 200 by 25 mm. test tubes), centrifugating, washing two more times with salt solution

quently killed or injured. Ruptured cells were not included in the counts. With each different lot of defibrinated blood, controls with Locke's solution were made. These invariably showed practically all the polymorphonuclear leukocytes packed with cocci. Occasional small dead cells (from 2 to 4 per cent) with multilobulated nuclei were found in the controls. To control the primary toxicity of the potassium iodide in the compound solution of iodine, U. S. P., tests were carried out with a 5 per cent solution of iodine in 10 per cent sodium iodide.

The results of these tests are summarized in table 5. The toxicities of the iodine solutions were directly proportional to their iodine content. The leukocytes withstood a primary iodine concentration of about 1:1,100 for ten minutes. The iodine solution made with sodium iodide had a toxicity identical with that

coccic cysts usually appear in the lower lobes. If secretions are obtained either by aspiration or by expectoration, diagnostic hooklets may be found. The complement fixation test is useful in diagnosis. Urticaria and eosinophilia are distinctive features. Dermoid cysts originate generally near the mediastinum and do not develop until the age of puberty. Hair may be recovered from discharged cystic secretions. Too, roentgenograms may reveal dense structures, such as teeth and bone. Elimination of these various types, therefore, should not be difficult in the differential diagnosis.

#### TREATMENT

The kaleidoscopic clinical course, as well as the character, extent and location of the lesion, presents a difficult therapeutic problem. The measures employed depend on the age of the patient and the stage to which the disease has progressed at the time of discovery.

Asymptomatic fluid cysts are dealt with principally by prophylaxis or prompt therapeutics of concomitant respiratory infections. Therefore, rigid clinical and roentgenologic observation is indicated until the patient reaches an age when surgery may be safely undertaken. This allows a period of time to elapse during which a spontaneous cure may be established.

Miller,<sup>31</sup> Zdansky,<sup>54</sup> Melchior,<sup>60</sup> Sauerbruch,<sup>61</sup> Braeuning,<sup>62</sup> Harrington<sup>63</sup> and Clairmont<sup>64</sup> have found removal of fluid cysts in toto eminently effective in selected cases. Lobectomy has also proved satisfactory. When infection exists, treatment as for any lung abscess is indicated.

In balloon cysts, thoracentesis has been employed successfully by Crosswell and King,<sup>12</sup> Vollmer<sup>47</sup> and Fleming,<sup>65</sup> but was ineffectual in cases of Pearson<sup>13</sup> and Wood.<sup>32</sup> It may serve, however, to prevent a fatal accident until more radical measures can be applied. Adams<sup>66</sup> emphasized the importance of attaching to the needle a rubber tube and placing its end under water, thus maintaining equalized intrathoracic pressure. Iodized oil should be injected into the cyst at the first thoracentesis. Single aspirations are of no value; in fact, they may prove harmful.

Surgery probably will meet the demand for cure of expansile cysts. However, Eloesser's<sup>59</sup> patient died of postoperative shock when a balloon cyst was removed, and Graham<sup>66</sup> was unsuccessful in his attempt to suture the bronchial opening by way of the transthoracic route. The use of the thoracoscope, or straight cystoscope, and cauterization of the aperture with sclerosing solutions or other destructive agencies, according to the method of Adams,<sup>66</sup> seems to us the most logical and hopeful surgical approach.

Multiple cysts lend themselves less readily to therapy than do solitary cysts. Should these lesions fail to respond to sclerosing solutions, surgery is the best treatment. Operation is likewise necessary in the majority of cases complicated by infection. Many patients, however, show little effect of the infection, as is shown in reports by Gibson,<sup>67</sup> Ehlers<sup>68</sup> and Miller.<sup>31</sup> The most popular procedures are postural and bronchoscopic drainage, and vaccines. These, however, are

seldom curative. When the cysts involve an accessible portion of the lung, lobectomy may be employed. Phrenic interruption has been attempted in an effort to collapse the cavity. Pneumothorax has been tried, but with dubious success.

#### PROGNOSIS

An analysis of the reported cases of congenital lung cysts indicates a high mortality rate in infants and children. Of the total of 152 reported since 1925, forty-six of the patients were under 3 years of age. Of the forty-six, thirty-six are dead. A record of cure is available in only seven of the remaining ten. We note, however, that a far higher percentage of deaths occur in the first two years of life, probably because of the poorly developed accessory muscles of respiration, the flexible infant mediastinum, and the inability of the lung tissue to withstand the pericystic pressure. The overwhelming infection present in some cases is also a factor.

Fluid cysts, it seems, do not of themselves carry a grave outlook, but the development of infection and the establishment of bronchial communication are fatal complications.

It follows, then, that the prognosis of a given case of congenital lung cyst, like the treatment, is governed by

Fig. 6.—Mechanism of action of the types of bronchial communication. A 1, check valve allows ingress of air on inspiration; A 2, expiration—closure of bronchial opening by flap prevents egress resulting in expansile air cyst. B, bypass valve allows ingress and egress of air; result, non-expansile air cyst. C, large free opening results in collapse of cyst with spontaneous recovery.

the age of the child and the stage of the disease when recognized.

#### SUMMARY AND CONCLUSIONS

Although an increase in reported cases of congenital cystic disease of the lung has occurred during the past decade, many more probably would be discovered if the condition were kept in mind and the proper method of examination employed. We have discussed the embryologic, physiologic and pathologic background of the disease and presented a graphic outline of the various states encountered in its course. It is our opinion that the condition is the result of some anomaly that interrupts the canalization of a ramification in a bronchial radicle in the embryo and that the portion thus separated later develops into a stunted structure retaining bronchial characteristics, the entrapped secretory mucosa of which furnishes the fluid for the cyst found at birth. The subsequent clinical behavior has no bearing on the congenital factors of its production but is dependent on the development and extent of infection and, if any, the type of bronchial communication established.

The symptomatology, diagnosis, differential diagnosis and methods of treatment have been presented in detail. We wish to stress, particularly, the point that, once a diagnosis is made, a careful clinical and roentgenologic

The nontoxic intradermal doses are included in table 5. Those of the iodine and miscellaneous groups agree with their respective dilutions that were nontoxic for leukocytes, within the limits of error of both tests. The mercury solutions were much more toxic on intradermal injection than they were in the whole blood mixtures, whereas in the chlorine group the reverse was found to hold true. From these observations it would seem reasonable to conclude that the compounds resulting from the combination of body proteins with antiseptics of the iodine and miscellaneous groups are relatively innocuous, that those formed with mercury solutions are able to cause necrosis and that human polymorphonuclear leukocytes are particularly susceptible to antiseptics belonging to the chlorine group.

## COST

A list of the antiseptic solutions was sent to two reputable retail pharmacists with the request that they furnish the retail price of the different solutions, based on a unit volume of 8 ounces (240 cc.). In the case of proprietary antiseptics which were not marketed in this size bottle, it was asked that the price of a bottle nearest 8 ounces be given, together with the volume of its contents. In one instance in which the product had not been nationally marketed, the retail price was obtained from the manufacturer.

TABLE 6.—Cost

Antiseptic Solutions	Size	Retail Price		Average Unit (8 Oz.) Price
		Pharmacy	Manufacturer

\* Indicates on prescription only.

The unit costs, listed in table 6, were obtained by averaging the costs from the two lists. Where dilution was necessary, no extra expense was added. In general, the unit prices of the mercury solutions were the highest and the miscellaneous solutions were next. The chlorine solutions and the iodine dilutions were by far the least expensive. While it is realized that these costs do not represent those of a hospital or even of the physician, they do give some idea of the relative expense to the patient.

## COMMENT

The tests here reported were selected or devised with the purpose of measuring certain prerequisites that seemed to be desirable in antiseptics used in wounds,

on cuts and abrasions and for irrigations. As the methods differ from the majority of those used by other investigators, no attempt will be made to correlate the results in detail.

In brief, it may be said that the bactericidal potencies are much lower than those previously reported. This is partly explained for all solutions by the choice of the highest dilution killing in five minutes as the bactericidal limit, rather than that killing in ten minutes but not in five minutes. The potency of the mercury solutions was reduced even further by eliminating the bacteriostatic effect more effectively than has been done before in the majority of instances. Similarly, the potencies in the presence of serum are lower, as a result not only of the foregoing but also of the use of 50 per cent serum in the mixtures. No reference has been found in which diffusibility and toxicity have been determined by the methods used in this paper. Salle and Lazarus<sup>3</sup> have recently compared several antiseptics with regard to toxicity for chick embryo tissue cultures and to bactericidal activity against *Staphylococcus aureus*, but such comparison does not appear valid, in that the antiseptics were in contact with the tissue cultures for forty-eight hours and with the cocci for ten minutes, and in that the solutions used to determine bacteria killing power were not serum mixtures.

The method used to estimate penetration is far from ideal. One is concerned with the penetration of animal membranes, but the standardization of such membranes seemed to be impractical. The factors governing penetration of cell membranes are much more complex than those concerned in diffusion through collodion membranes. With the latter, as shown in the tests, the diffusion rate is more rapid in solutions of simple inorganic compounds of relatively small molecular size. From analogy and with certain qualifications the same probably holds true for the penetration of animal membranes, although no experimental proof has been given.

When one considers this group of experiments as a whole, the superiority of iodine as an *in vitro* antiseptic is obvious. The bactericidal strength of any iodine solution is directly proportional to its free iodine content. It is the only antiseptic of the series that is potent in the presence of an equal amount of serum. It is diffusible and is not unduly toxic for human leukocytes. In dilutions that are suitable for their particular purposes it is inexpensive. In other words, solutions of iodine possess the prerequisites that were considered desirable for an antiseptic solution to be used in wounds, on cuts and abrasions and for irrigations.

A certain antipathy has arisen to iodine because of the fact that it is usually employed as the standard (7 per cent) or half strength (3.5 per cent) tincture. Such a solution is painful to apply and irritating, owing partly to the high iodine content and partly to the alcohol. The use of aqueous iodine solutions has been recommended but has not been generally accepted. By referring to the tables, it will be seen that even a 1:6.4 dilution of compound solution of iodine, U. S. P., is much more active *in vitro* than any of the other types of antiseptic solutions. This suggests that a 1 per cent or even a 0.5 per cent aqueous solution, containing the necessary amount of potassium or sodium iodide for solution, can be used to advantage in wounds and

3. Salle, A. J., and Lazarus, A. S.: Comparison of Resistance of Bacteria and Embryonic Tissue to Germicidal Substances. *Proc. Soc. Exper. Biol. & Med.* 22: 665 (Feb.), 937 (March), 1957, 1119 (April) and 1481 (June) 1935.

relatively little significance when applied to solutions to be used in wounds, on cuts and abrasions or for irrigations. In all these instances the antiseptic is in contact with blood, lymph, tissue juice or secretions of the mucous membranes and its bactericidal power must be measured in the presence of one or another of these substances. This type of antiseptic should possess a certain degree of penetration. Ideally, it should be able to kill bacteria in at least as high a dilution as it does normal tissue cells—in other words, its toxicity for tissue cells should be no greater than its bactericidal power. Finally, its cost should be reasonable.

As has already been mentioned, hundreds of articles have appeared in medical literature during the past ten years in which one or more of these essential properties have been determined. Such papers have usually featured one antiseptic, and comparison has been made with only a few other solutions. Furthermore, effective dilutions have always been expressed in terms of the solid salt or compound. This is apt to be misleading, for dilutions in such instances are significant only when the usable dilution is taken into account. For example, usable dilutions of compound solution of iodine, U. S. P., and mercury bichloride are 1:20 and 1:1,000, respectively. If it is assumed that the highest bactericidal dilutions are found to be 1:4,000 and 1:20,000, respectively, at a casual glance it would appear that the mercury bichloride solution is five times as bactericidal as the iodine solution. The iodine solution, however, is actually ten times as strong as the mercury bichloride solution, for 1:4,000 is a 1:200 dilution of the usable strength of the former and 1:20,000 is a 1:20 dilution of the usable strength of the latter. In other words, the usable iodine solution can be diluted 200 times and still be bactericidal, whereas the usable mercury solution can be diluted only twenty times.

As alcohol or alcohol and acetone are undesirable and unnecessary in antiseptic solutions for minor wounds and irrigations and, in addition, are of themselves bactericidal in low dilutions, aqueous solutions, with two exceptions, were employed in the series. The different antiseptics are herewith listed:

#### LIST OF ANTISEPTICS EMPLOYED

All proprietary solutions were purchased, when possible, in the open market. The nonproprietary solutions were prepared in this laboratory. In each instance the usable strength is given. The dilutions noted in the subsequent results refer to dilutions of the respective usable dilutions.

#### SOLUTIONS CONTAINING IODINE

1. Compound solution of iodine, U. S. P. Usable strength undiluted. Iodine content 5 per cent (1:20) when titrated with a standardized tenth normal sodium thiosulfate solution.
2. Iodine solution (nonalcoholic). Usable strength undiluted. Iodine content 0.78 per cent (1:128), titrated as above. Submitted by Amend Laboratories, Inc., New York.
3. Compound solution of iodine, U. S. P., diluted 1:6.4. Usable strength undiluted. Iodine content 0.78 per cent (1:128), titrated as above.
4. Compound solution of iodine, U. S. P., diluted 1:27.8. Usable strength undiluted. Iodine content 0.18 per cent (1:555), titrated as above.

#### SOLUTIONS CONTAINING MERCURY

1. Metaphen (1:500). Usable strength undiluted. Manufactured by Dermatological Research Laboratories, Philadelphia.
2. Merthiolate (1:1,000): Usable strength undiluted. Manufactured by Eli Lilly & Co., Indianapolis.

3. Mercurochrome (1:50). Usable strength undiluted. Salt manufactured by Hynson, Westcott & Dunning, Inc., Baltimore. Solution prepared in the dispensary, Boston City Hospital.

4. Mercuric oxycyanide ("containing mercury cyanide"—Merck) (1:4,000). Usable strength undiluted.

5. Mercury bichloride (Vaichulis-Arnold modification,<sup>1</sup> aqueous) (1:1,000). Usable strength undiluted.

6. Merphenyl nitrate (1:1,500). Usable strength undiluted. Obtained through the courtesy of Hamilton Laboratories, Inc., Hamilton, Ohio.

7. Merphenyl borate (1:500). Usable strength undiluted. Obtained through the courtesy of Hamilton Laboratories, Inc., Hamilton, Ohio.

#### SOLUTIONS CONTAINING CHLORINE

1. Zonite. Usable strength 1:2. Available chlorine content (diluted) 0.53 per cent (1:190), titrated, after conversion to iodine, with a standardized tenth normal sodium thiosulfate solution. Manufactured by Zonite Products Corporation, New Brunswick, N. J.

2. Apco No. 25, diluted 1:8.3. Usable strength undiluted. Available chlorine content 0.39 per cent (1:260), titrated as above. Dilution made in the dispensary, Boston City Hospital. Manufactured by Ampere Products Company, West Orange, N. J.

#### MISCELLANEOUS SOLUTIONS

1. Hexylresorcinol (1:1,000). Usable strength undiluted. Manufactured by Sharp & Dohme, Baltimore.

2. Listerine (25 per cent alcohol). Usable strength undiluted. Manufactured by Lambert Pharmacal Company, St. Louis.

3. Pepsodent (25 per cent alcohol). Usable strength undiluted. Manufactured by Pepsodent Company, Chicago.

All these antiseptics were tested simultaneously for (1) bactericidal activity, (2) bactericidal activity in mixtures containing 50 per cent horse serum; (3) diffusibility and (4) toxicity. In addition, figures representing unit costs were obtained. The methods employed and the results obtained are given in the following sections.

#### BACTERICIDAL ACTIVITY

As a measure of bactericidal activity the "F. D. A. method (special) *S. aureus*, 37 C.," as recommended by the Food and Drug Administration and described in circular 198 (December 1931), U. S. Department of Agriculture, was followed explicitly with two exceptions. In the first place, the highest dilution killing in five minutes was considered the limit of bactericidal activity, rather than the highest dilution killing in ten minutes but not in five minutes. This modification seemed advisable for two reasons; namely, that the effective action of any antiseptic in the ordinary wound was probably less than ten minutes and that the technic of the test was simplified. Secondly, standardized pipets were not used in making the dilutions, as it was felt that the accuracy so afforded was not necessary when equal amounts of diluent were added for succeeding dilutions. The culture of *Staphylococcus aureus* was obtained from the Food and Drug Administration Laboratories in Washington. In all the separate tests for bactericidal activity and in all subsequent tests in which live bacteria were used, the resistance of the culture was assured by control tests with 1:80 and 1:90 dilutions of phenol, prepared from a standardized 5 per cent phenol solution.

The method, in brief, consists of adding 0.5 cc. of a twenty-two to twenty-six hour culture of *Staphylo-*

between the twentieth and the fiftieth day, usually about the thirtieth day, shown in table 2 and in the accompanying charts. The amount of hormone excreted at the peak seems to differentiate our cases into two groups: one in which total unitage per day is perhaps between 75,000 and 150,000 rat units, and another group in which it is between 750,000 and 1,000,000 units.

Concentration of gonadotropic principle in six cases.

Equally remarkable is the abrupt decrease in the concentration of gonadotropic hormone after the maximum has been reached. In all but one case the hormone concentration is below 10,000 rat units per liter by the sixty-fifth day and continues at or below this level until the termination of pregnancy. The amount of hormone excreted per day is therefore low during the last two thirds of pregnancy as compared with that involved in the ascent, summit and descent from the peak, all of which occur in the first two months. It is undoubtedly due to their transient presence and to the lack of sufficiently careful titrations that the regular occurrence of these high urinary hormone values has been previously overlooked.

It is unnecessary to comment on the speed with which the body frees itself of gonadotropic hormone following parturition because this fact is already well established. By the fifth day following parturition there is no trace of the hormone in the urine.

It is highly interesting that the urinary "peak phenomenon" herein reported is paralleled by the hormone levels of the blood. In case 5 on the thirty-seventh day the blood serum contained 100,000 rat units per liter of hormone and the urine exactly the same titer. In case 6 on the fortieth day the blood serum contained 500,000 units per liter of hormone with an identical level in the urine.

That the early normal tremendous rise in the hormone content of urine and blood is not an indication of toxicosis<sup>3</sup> is shown by the fact that in the two cases which exhibited the phenomenally high concentrations there was practically no indication of the minor disturbances commonly occurring in the early part of pregnancy, while patients with lower concentrations experienced these minor disturbances, such as varying degrees of nausea and discomfort during the early months of gestation. There is even a suggestion here that a higher hormone level is protective.

The great difference in hormone concentration between the two groups cannot be accounted for on the basis of the sex of the fetus, for patient 1 with a maximum daily excretion of 75,000 rat units, patient 2 with over 1,000,000 rat units and patient 3 with 100,000 rat units all gave birth to females. Since patients 1, 3 and 6 were multiparas while patients 2, 4 and 5 were primiparas, it is obvious that the factor of previous pregnancies is not involved. Since the cause of the

normal hormone peak is obscure, it is obvious that conclusions can hardly be hazarded as to the cause of the striking variation in the height of the peak.

3. Ehrhardt<sup>4</sup> is unaware of the "peak phenomenon" but familiar with occasional surprisingly high levels of urinary hormone in normal early pregnancy. He reports, for instance, encountering a normal case of 70,000 mouse units per liter between the first and the second month. Although he therefore speaks guardedly, he has associated the vomiting in the first to the third month with "high" hormone content of the urine, which his figures show to have varied from 20,000 to 150,000 units in his cases.

whereas with the two weaker solutions the next lower dilution was required to kill. With the weakest iodine solution, even the second lower dilution was ineffective. This suggested that the weaker the iodine solution the greater the percentage neutralization of the iodine by the serum. In order to confirm this observation, mixtures of equal parts of horse serum and compound solution of iodine, U. S. P., undiluted and diluted 1:8 and 1:32, were made and the amounts of iodine in samples removed at seven minutes, one hour, two hours and three hours were titrated with tenth normal sodium thiosulfate. The results of these titrations are shown in table 3. The total amount of free iodine in each at

prepared by dissolving 30 Gm. of Parlodion (Mal-linckrodt) in 250 cc. of a mixture of equal parts of ethyl alcohol and sulfuric ether. Each sac was stand-ardized for its permeability by determining the amount of iodine passing into the dialysate from a measured amount of compound solution of iodine, U. S. P., in a definite period of time. Only sacs deviating less than 25 per cent above or below the arbitrarily chosen standard were used in the test.

The sacs were sterilized by immersion in a 1:25 dilution of compound solution of iodine, U. S. P., over night. A calculated amount of sterile tenth normal sodium thiosulfate was added which was slightly in

the end of one hour was decreased 23, 58 and 85 per cent, respectively. These figures correspond to the observed changes in bactericidal activity of the iodine solutions brought about by the addition of 50 per cent horse serum.

Titration of available chlorine in a mixture of equal parts of horse serum and one of the chlorine solutions showed a diminution in one hour of less than 50 per cent. Bactericidal activity, however, was diminished more than 95 per cent. This would seem to indicate that some combination or reaction had taken place which rendered the antiseptic ineffectual as a bacteria-killing agent, in spite of the persistence of presumably adequate amounts of available chlorine.

DIFFUSIBILITY

Parlodion sacs were made in test tubes having an internal diameter of 16 mm. The solution used was

excess of that needed to remove the free iodine. After the iodine color had disappeared from outside and inside the sacs, each was washed twice in sterile dis-tilled water and blotted relatively dry between large sheets of sterile filter paper. Twelve cubic centimeters of antiseptic was placed in each sac and the sac placed in a 150 by 25 mm. test tube containing an equal

added to the excellent contributions of Downey and McKinlay<sup>3</sup> and Downey and Stasney.<sup>12</sup>

The report is based on a serologic study of thirty cases of infectious mononucleosis, of seventeen cases of serum disease, of a group of borderline cases which were indistinguishable from infectious mononucleosis clinically and hematologically, and of a series of normal controls with a negative history as to infectious mononucleosis and horse serum injection.

#### ABSORPTION

The serum is heated for thirty minutes at 56 C. Portions of the serum are absorbed with the following antigens: kidney of the guinea-pig and of the rabbit, beef heart, sheep erythrocytes, beef erythrocytes, and kaolin. The kidneys are kept frozen in the refrigerator until needed. They are then thawed and washed repeatedly in physiologic solution of sodium chloride until the washings are free from blood. They are now mashed into a fine pulp and used for absorption as a 20 per cent suspension in physiologic solution of sodium

chloride. The suspensions are boiled for one hour on the water bath, and the loss by evaporation is made up with distilled water.

For the beef heart suspension the product of the Digestive Ferment Company is used. The suspension is not boiled.

The sheep and beef red cells are washed three times, packed well in the centrifuge, suspended in four volumes of physiologic solution of sodium chloride and boiled for one hour on the water bath. The loss by evaporation is made up with distilled water. The kaolin is also used as a 20 per cent suspension in physiologic solution of sodium chloride. This suspension is not boiled. Enough phenol is added to all antigenic suspensions to make a 0.5 per cent solution. The antigens may be kept in the icebox for many months without a noticeable change.

For absorption, different quantities of the antigens are added to the serum; the mixtures are kept at room temperature for one hour and shaken vigorously at intervals of fifteen minutes. They are then centrifugated and the clear supernatant serum is transferred to other test tubes.

Two series of absorptions were carried out with different techniques. In one series the serum was absorbed

with the varying amounts of the antigens (from 0.03 to 0.12 cc. to 0.1 cc. of serum). After the absorption a quantity of the serum sufficient for the various titrations was removed and a second absorption carried out by treating the remainder of the serum with an equal amount of the suspension of the antigen. Again, enough serum was removed to study the effect of the second absorption. The third and further absorptions were then carried out. The effect of the repeated absorptions on the dilution of the serum was taken into consideration. This repeated absorption supplied the quantitative data concerning the relation between the absorbing antigen and the absorbed antibody.

In the second series of absorptions, the serum (in quantities of 0.1 cc.) was treated only once with varying amounts of antigens.

#### TITRATION

Dilutions of the untreated and of the absorbed serum ranging from 1:5 to 1:5,120 or more are set up. The total quantity of the dilution is 0.25 cc.; 0.1 cc. of a 2 per cent suspension of washed sheep cells is added. The tubes are left at room temperature for two hours. The tubes are shaken vigorously until the sediment of the cells becomes suspended. The reading is done with the low power of the microscope (32 mm. objective). The titers as they are recorded represent the so-called one plus reading and signify distinct microscopically discernible clumping. A difference of about one dilution may result when the reading is done with the naked eye. The titers are estimated in the terms of the final dilutions (see table 1 in a previous publication<sup>9</sup>).

Table 1 brings out the details of the test for infectious mononucleosis. The last columns list the incidence of titers in my series.

#### THE RESULTS OF THE ABSORPTION STUDIES

Serum from normal persons, from patients with serum disease, and with infectious mononucleosis was absorbed with different antigens. The titers of the sheep agglutinins were determined before and after the absorptions. The effect of the absorption was expressed in the percentages of the antibodies that were removed.

As stated, agglutinins for sheep erythrocytes are found in low titers in the blood serum of most normal persons. In a previous series<sup>9</sup> they were below the lowest titer of 1:3.5 in only 7 per cent of 217 normal persons, and in only 1 per cent of them was the titer 1:56, while the remainder had titers varying from 1:3.5 to 1:28.

The titers of the serums of five normal persons varied from 1:14 to 1:28, the average titer being 1:20. The kidney of the guinea-pig and the erythrocytes of the sheep, both carriers of the Forssman antigen, removed completely the agglutinins for the sheep red cells. The kidney of the rabbit and the erythrocytes of the beef absorbed on the average 35 per cent of the agglutinins. The results are in accord with the well known fact that the agglutinins for sheep erythrocytes in normal persons are of the Forssman heterophilic type. The inability of beef erythrocytes to remove the heterophilic agglutinins is worthy of note, mainly in view of their different action in mononucleosis.

Four serums of patients with serum disease were absorbed with the antigens repeatedly until the agglutinins for sheep erythrocytes were completely removed, and three serums were absorbed only once with an ade-

of compound solution of iodine, U. S. P. The chlorine solutions were extremely toxic and the mercury solutions varied from no toxicity to moderate toxicity. The miscellaneous solutions were only moderately toxic. The two containing alcohol behaved quite similarly in that there were many secondarily killed leukocytes, which suggests that the alcohol or some other common ingredient was responsible. Cells killed after the addition of the cocci were also noted in preparations from both chlorine solutions and two of the mercury solutions.

A consideration of the toxicity of each antiseptic as compared with the bactericidal activity is of the

each 0.6 cc. of the mixture contained 0.5 cc. of blood and 0.1 cc. of culture. Transfers were made after ten minutes' incubation at 37 C. Second transfers were made in the usual way. Stained smears of the blood and culture mixture showed no phagocytosed cocci.

The results are given in table 5. It will be seen that neither the strongest dilutions permitted survival of the leukocytes, nor those twice as strong that killed over 50 per cent of the leukocytes were able to kill all the staphylococci. With the three strongest iodine solutions the staphylococci were killed in the mixtures made with the lowest dilutions. None of the mixtures with the other antiseptics were bactericidal. In three, which had

utmost practical significance. The results given in table 2 cannot be taken as comparative measures of bactericidal activity, for the method varied considerably from that used in determining toxicity. In order to make an equitable comparison, the bactericidal test was repeated, mixtures of equal amounts (0.5 cc.) of sterile defibrinated human blood in which the leukocytes were dead and three dilutions of the antiseptic solutions being used. The latter were such that the highest dilution was the lowest permitting the survival of 50 per cent of the leukocytes and the other two were the two next stronger. With nontoxic solutions only the undiluted antiseptic was used. The culture of *Staphylococcus aureus* was mixed with defibrinated blood so that

such a high toxicity that mixtures with the undiluted solution were not included in the test, such mixtures were tried, and even these failed to show killing power.

As a further check on toxicity, 0.2 cc. amounts of different dilutions of all the solutions were injected intradermally on the cleanly shaved abdomens of several rabbits. White rabbits of approximately the same age and size were used for each test, and 24 gage needles were used for each injection. All the undiluted antiseptics caused necrosis. Dilutions of each were made until no lesion or a questionable lesion was observed at the site of inoculation six days after the injection. The lowest dilution producing no necrosis was taken as the nontoxic intradermal dose.

patients with an atypical, frequently very severe and alarming course and with rare complications. Here belong also the patients who do not show the usual increase in the numbers of the mononuclear cells in the early stages of the disease.

**CASE 2.—Infectious mononucleosis resembling agranulocytosis.** A college student, aged 18 years, had been taking for some time aminopyrine for menstrual pains and headaches. She was suddenly taken ill with chills, fever, swelling of the cer-

vical lymph nodes and an ulcerative lesion of the pharynx. The white blood count was 1,500, with 15 per cent granulocytes. The diagnosis of agranulocytosis was made. It was then decided to carry out the agglutination test for heterophilic antibodies. It was strongly positive (1:896+). The diagnosis was changed to infectious mononucleosis. The patient recovered soon afterward. The leukopenia disappeared early; the white count on the fifth day was 9,300. The mononucleosis persisted for many weeks and showed from 60 to 80 per cent lymphocytes.

**CASE 6.—Infectious mononucleosis with features of an acute abdominal condition and of an acute leukemia; absence of a mononucleosis in the first blood count.** A college student, aged 18 years, was admitted, complaining of severe abdominal pains, nausea, vomiting and fever. Six weeks before admission she had a skin eruption diagnosed as measles. The lymph nodes of the neck were slightly enlarged but not tender. The left upper part of the abdomen was extremely tender. Blood examination revealed 6,720 white blood cells, with 51 per cent neutrophilic and 3 per cent eosinophilic leukocytes and 46 per cent lymphocytes. On the following day the fever assumed a septic character. The percentage of mononuclear cells rose to 58. An acute abdominal condition was suspected. An exploratory operation was considered imminent if improvement should not take place in a few days. Six days later a marked change in the blood took place: the white cells rose to 12,600 and the mononuclear cells to 93 per cent; 8 per cent among them resembled lymphoblasts. That, together with the serious clinical condition, made it necessary to consider acute leukemia. However, the test for infectious mononucleosis was then found to be positive (1:224). The attending physician was thus able to give a favorable prognosis. The patient made a rapid and uneventful recovery and has been well since. Various laboratory tests were negative. They included blood cultures, blood chemistry, Wassermann and Kahn tests, coagulation and bleeding time, and agglutinations for typhoid, paratyphoid, dysentery and undulant fever. Repeated blood counts were carried out during the patient's illness (table 5). The mononucleosis persisted until her discharge. It varied from 80 to 93 per cent.

In this case the agglutination test established the diagnosis of infectious mononucleosis; without it the patient might have been subjected to an exploratory operation.

**CASE 12.—Infectious mononucleosis with an acute gastritis, hepatitis, jaundice, with a severe toxemia and acute heart failure.** A man, aged 37, was admitted complaining of gastric distress for about six weeks. He lost 6 pounds (2.7 Kg.) in the last two weeks. He had a history of rheumatic heart disease in the past. Moderate jaundice, slightly enlarged but not tender lymph nodes of the neck and axillae, and an enlarged spleen and liver were found. The heart was enlarged and the

changes were those of a mitral endocarditis. There were 16,250 white cells with 84 per cent mononuclear cells and among them 8 young cells resembling lymphoblasts. The temperature kept on rising steadily, the pulse rate went up to 150 and the patient became very toxic. Pulmonary edema developed and the patient was considered critically ill. In addition to an acute endocarditis, acute leukemia, and infectious hepatitis were considered. At that time the high percentage of lymphocytes in the differential blood smear suggested the test for infectious mononucleosis. It was strongly positive (1:896). The result surprised all who attended the case and was accepted with a considerable measure of doubt. On the seventh day a dramatic turn for the better took place, with a sudden drop of the temperature. The jaundice reached a maximum on the ninth hospital day (icterus index 42 with a biphasic van den Bergh reaction) and then declined gradually. The patient was discharged on the twenty-fourth day. He remained well. His blood was studied repeatedly after his discharge during a period of 296 days (table 5).

The acute heart failure in an individual with a damaged myocardium brought about by the severe toxemia was a striking feature of the case.

These three cases are of the type in which the diagnosis of infectious mononucleosis would have been very difficult without the serologic test; only the later course might have suggested it.

Another form of diagnostic difficulties is encountered in cases that are indistinguishable from infectious mononucleosis clinically as well as hematologically and can be separated from it only by means of the serologic test, as the following case history will illustrate:

**Lymphocytic angina with a low titer of heterophilic antibodies; test for infectious mononucleosis negative.** A boy, aged 8 years, was taken ill with a sore throat and fever. His cervical lymph nodes were markedly enlarged and tender. The blood smear on the fifth day of illness showed polymorphonuclear leukocytes 22 per cent, eosinophils 1 per cent, lympho-

cytes 69 per cent, abnormal lymphocytes 1 per cent and monocytes 7 per cent (77 per cent mononuclear cells). The blood picture was indistinguishable from that generally seen in infectious mononucleosis and the clinical appearance was like that of mononucleosis; however, the agglutination test for mononucleosis was negative (1:7+). The child recovered rapidly.

In this case the low titer of agglutinins for sheep cells made it easy to exclude infectious mononucleosis. The decision is difficult in the third group, in which the clinical and hematologic picture suggests infectious mononucleosis and the titer of agglutinins for sheep

TABLE 1.—Weights and Characteristics of Ovaries in Rats  
Injected with Various Dilutions of Urine from Case 6  
at the Peak of Hormone Secretion, 750,000  
Rat Units per Day

2. Zondek, for instance, states that suspicion of the pathologic alteration of pregnancy may justifiably occur if the morning urine contains more than 50,000 mouse units per liter of the hormone (Zondek,<sup>1</sup> p. 367). Aschheim declares: "Values of more than 100,000 mouse units per liter point to the presence of hydatid mole with great probability" (Aschheim, Selmar: Pregnancy Tests, J. A. M. A. 104: 1324 [April 13] 1935).

result of the test was accepted with considerable skepticism. When seen by me two months after the onset, the patient was worried over the possibility that he may have had agranulocytosis. The agglutination test for sheep cells was 1:56+. The differential test showed failure of the guinea-pig kidney to remove the agglutinins and their removal by beef cells, indicating that the patient was recovering from infectious mononucleosis.

The results indicate the persistence of the quality of the antibodies in infectious mononucleosis even at a time when they are quantitatively indistinguishable from the normal agglutinins for sheep cells. It is therefore necessary to employ the differential test in cases that suggest the possibility of mononucleosis even if the titer of the agglutinins is less than 1:112.

#### HOW LONG DO THE HETEROPHILIC ANTIBODIES PERSIST IN INFECTIOUS MONONUCLEOSIS?

It was attempted to answer the question How long do the heterophilic antibodies persist in infectious mononucleosis? by a study of those cases which could be followed until the titers of the agglutinins for sheep cells returned to the normal level. Ten cases were followed up with blood counts and serologic tests. Only two will be reviewed in detail and then a summary of all ten cases will follow.

Table 4 shows the course of two such cases. The history of case 12 was presented previously. This patient was ill for forty-five days with gastric symptoms when the test was made. On the sixty-eighth day the titer was 1:112 and on the one hundred and seventeenth day it was still at the critical level of 1:56. On the next examination, on the two hundred and ninety-sixth day, the titer was within the normal limits (1:14). The so-called abnormal lymphocytes disappeared between the sixty-eighth and the ninety-second day, while the mononuclear count dropped to below 50 per cent at about the same time.

Case 17 might serve as another illustration. Here the drop of the titer from 1:224 to 1:56 occurred between the thirtieth and the forty-second day, and by the fifty-seventh day the titer fell to the normal level.

Table 5 summarizes the course of hematologic and serologic events in the ten patients. The clinical improvement was not always synonymous with a complete recovery but coincided in most cases with the discharge of the patient from the hospital. It paralleled quite closely the disappearance of the so-called abnormal lymphocytes. The drop of the mononuclear cells to below the 50 per cent level came about somewhat later. The number of 50 per cent was chosen arbitrarily as a rough indicator of a return to approximately normal relations. The disappearance of the abnormal lymphocytes and the return of the mononuclear count to below the 50 per cent level could be referred to as the hematologic recovery that followed the clinical recovery and was in turn followed by the serologic recovery, the latest of the three. The first finding of the normal titer of less than 1:56 varied from fifty to 296 days (average 119 days) after the onset of illness in the eight cases in which it could be observed.

The fifth and final group of cases in which the value of the differential test becomes particularly apparent are those with a history of a recent injection of immune horse serum and especially those with serum disease. In such a case the question arises whether the elevated titer of the heterophilic antibodies is due to infectious

mononucleosis or to the serum injection. The following case belongs to that group:

CASE 27.—*Infectious mononucleosis with involvement of the central nervous system and complicated by serum disease.* A high school girl, aged 16 years, contracted a cold about Nov. 20, 1935. When she was seen by her physician two weeks later she had a high fever, a sore throat, and enlarged and tender cervical lymph nodes. The physician was called two days later and found the girl unconscious and in convulsions. The patient was admitted to the hospital, where the cerebrospinal fluid was found clear, with 18 cells per cubic millimeter. Antimeningococcus serum was given. The patient continued to be very restless and unconscious. On the third day after admission, she became conscious. An ulcerative and membranous pharyngitis set in at that time. The white blood count showed on admission 8,500 cells, with 60 per cent polymorphonuclear leukocytes and 40 per cent lymphocytes. In the course of the next few days the blood showed 54 per cent and later 61 per cent mononuclear cells, with 2 per cent of so-called abnormal lymphocytes. Four days later, the patient developed serum disease. A few weeks later when the encephalitic symptoms had subsided, the blood examination suggested the possibility of infectious mononucleosis. December 27 the test was strongly positive (1:896). The interpretation of the test was complicated by the history of recent serum disease. The high titer of the agglutinins for sheep cells could have been due to serum disease. The differential test showed complete absorption of the sheep agglutinins by beef cells and only partial removal by the guinea-pig kidney and established the diagnosis of infectious mononucleosis. The patient was followed hematologically and serologically for 135 days (table 5). The complicating involvement of the central nervous system and the absence of an elevated mononuclear count in the beginning of the disease are notable features.

#### CONCLUSIONS

The test for heterophilic antibodies is of confirmatory diagnostic value in cases of infectious mononucleosis with typical clinical and hematologic features.

It is of a deciding diagnostic importance (a) for the early recognition of cases that show unusual hematologic signs and clinical symptoms, some of which are due to complicating factors, and (b) for the exclusion from the group of infectious mononucleosis of cases that are otherwise clinically and hematologically indistinguishable from it.

The differential test for infectious mononucleosis is of deciding diagnostic value (a) for the exclusion of cases that are clinically and hematologically indistinguishable from infectious mononucleosis and that have a so-called borderline titer of heterophilic antibodies (1:56 or 1:112); (b) for the recognition of late cases of infectious mononucleosis with a relatively low titer of heterophilic antibodies, and (c) for the recognition of cases that are complicated by a recent therapeutic injection of a horse immune serum or by serum disease.

5758 Kenwood Avenue.

#### ABSTRACT OF DISCUSSION

DR. RICHARD H. JAFFÉ, Chicago: There are two points in Dr. Davidsohn's paper in which I am much interested. I believe that the demonstration of the heterophilic antibodies suggests that infectious mononucleosis is a specific disease. So far some pathologists were inclined to consider infectious mononucleosis as the lymphatic reaction to any kind of infection, but now it seems to be a disease entity. Secondly, as Dr. Davidsohn has pointed out, the blood picture is not always characteristic, particularly in the early stages. There may be a polymorphonucleosis, and the demonstration of the heterophilic antibodies will help identify those cases in which the blood picture is not or not yet typical. As far as the blood picture is concerned, in some cases the characteristic large lymphatic cells are found. These lymphatic cells are not young lympho-

## CONCLUSIONS

1. Charts are presented showing the actual quantitative content of the urine in gonadotropic hormone at various times throughout six normal pregnancies.
2. The charts show the invariable existence of an exceedingly steep and high hormone peak at a time which is quite accurately one month from the beginning of the first expected but missed menstruation.
3. The peak must be recognized as a normal phenomenon in all studies attempting to relate high hormone levels with pathologic insignia.

## SEROLOGIC DIAGNOSIS OF INFECTIOUS MONONUCLEOSIS

ISRAEL DAVIDSOHN, M.D.  
CHICAGO

Infectious mononucleosis has been known under different names since 1889, when it was described by E. Pfeiffer<sup>1</sup> as glandular fever. Thirty-four years later, Tidy and Daniel<sup>2</sup> and Downey and McKinlay<sup>3</sup> described the characteristic blood changes and inaugurated the hematologic diagnosis of infectious mononucleosis. The blood changes are very helpful in the recognition of the disease, but they are not pathognomonic. Similar changes are found in several clinically unrelated diseases, particularly acute infections of the pharynx. Furthermore, in the early stages of infectious mononucleosis the characteristic elevation of the mononuclear cells may be absent and the blood picture may show merely a slight to moderate increase of the total number of white cells with a normal differential count.

A second phase in the diagnosis of infectious mononucleosis was initiated in 1932 by Paul and Bunnell,<sup>4</sup> when they found that the blood serum of the patients is able, even in high dilutions, to clump sheep red cells.

It has been known for a long time that the blood serum of a large majority of persons is able to lake and to clump the erythrocytes of the sheep, but only in very low dilutions.<sup>5</sup> It has also been known that the lytic and agglutinative power of human blood serum rises considerably after the injection of horse serum, normal or immune, particularly if followed by serum disease.<sup>6</sup> It was in the course of checking my observations in horse serum disease that Paul and Bunnell discovered the presence of similar antibodies in infectious mononucleosis.

The hemolysins and agglutinins of normal persons and of persons injected with horse serum are called heterophilic antibodies. The term "heterophilic" refers to the property of such antibodies to react with an

antigen (sheep erythrocytes) that seemingly had nothing to do with their development. They possess that property in addition to the ability to react with the homologous antigen. Some heterophilic antibodies are specifically removed from human or animal serum by the tissues of various animals (guinea-pig, horse, chicken and others) and by some bacteria (pneumococci, dysentery bacilli and others). The antigen in these animals and bacteria is known under the name of its discoverer as the Forssman heterophilic antigen. It is well to remember that there are varieties of heterophilic antigens and antibodies that differ from the Forssman type. Further information may be found in reviews of the subject.<sup>7</sup>

It was shown by proper absorption tests that the antibodies against sheep red cells in normal persons and after horse serum therapy are of the Forssman type and by analogy it was assumed by many writers that the antibodies in infectious mononucleosis are also of that type.

In February 1934 I presented before the Chicago Pathological Society a modification of the technic of the agglutination test for infectious mononucleosis that has greater speed and precision than the older technic that I employed previously in the study of serum disease.<sup>8</sup> I now began a study of the nature of the heterophilic antibodies in infectious mononucleosis and a preliminary report of my studies was given at the meeting of the American Society of Clinical Pathologists in June 1935.<sup>9</sup> It is of interest that similar investigations were carried on independently of each other by C. A. Stuart and his associates,<sup>10</sup> and by Bailey and Raffel.<sup>11</sup>

In view of the fact that nothing definite is known at present about the etiology of infectious mononucleosis and that the morphologic changes in the blood are characteristic but not absolutely specific for the disease, the study of the antibodies in the blood serum offers a basis for recognition as well as for classification of the disease. It may be that the finding of the etiologic factor will modify or even nullify the significance of the serologic changes in infectious mononucleosis. It may then become apparent that we are dealing here with more than one disease. However, until such time, considerable help can be derived from what is already known about the heterophilic antibodies in mononucleosis.

The purpose of my report is to demonstrate the value of the agglutination test in the diagnosis of atypical cases of infectious mononucleosis and to present a differential test for infectious mononucleosis which widens greatly the usefulness of the serologic diagnosis. The hematologic aspect of the diagnosis of infectious mononucleosis will not be discussed, because nothing can be

Age apparently has no effect in the demonstration of air under the diaphragm. The youngest patient in our positive group was a new-born white boy who had a perforated duodenal ulcer, bilateral inguinal hernia, pneumoperitoneum and pneumoserotum. The oldest patient was a white woman aged 71. There are practically equal numbers in each of the four decades between the ages of 20 and 60 years, but there are only three females in the entire group.

The roentgen technic employed is fortunately very simple. Brilliant films are by no means necessary. Most of the films in our collection have been exposed with a small mobile unit in the ward or operating room. The one absolute essential is that the patient be put in the upright position during the x-ray exposure. It is helpful to turn the patient on his left side for a short period before elevating the upper part of the body.

SUMMARY

The series of forty-two cases of proved perforated gastric and duodenal ulcers gave a positive roentgen diagnosis in thirty-five, or 83 per cent. It is important that the roentgen examination be made as soon as possible after the perforation, as the small amount of air present is soon resorbed. With all factors under better control, the percentage of positive results will probably be considerably higher. The method is of decided value in differential diagnosis and is entitled to more emphasis than is given it in textbooks of roentgen interpretation.

HEMOLYTIC TRANSFUSION REACTION PRODUCED BY  
THE BLOOD OF A "UNIVERSAL DONOR"

ELMER L. DeGOWIN, M.D., IOWA CITY

Since the blood of group O contains no agglutinogens, Ottenberg<sup>1</sup> in 1911 proposed the use of individuals of this group as "universal donors." It was thought that the agglutinins  $\alpha$  and  $\beta$  would be sufficiently diluted in the recipient's serum as to be ineffectual.

tion of 1:120. Freeman and Whitehouse<sup>4</sup> found a group O blood the  $\alpha$  agglutinin of which was active in a dilution of 1:80. The  $\beta$  agglutinin reacted in a dilution of 1:48. Neither of these bloods was actually used for transfusions. Thomsen<sup>5</sup> determined the hemolysin titer of twenty-four serums of group O and found that the majority hemolyzed A corpuscles in dilutions of 1:4, although one was potent in a dilution of 1:64 and two were potent in a dilution of 1:16. In general, the  $\alpha$  hemolysin was more potent than the  $\beta$ .

Hemolytic reactions from the transfusion of group O blood into recipients of other types have been reported by Unger,<sup>6</sup> Wichels and Lampe,<sup>7</sup> Tiber<sup>8</sup> and many others. Hesse<sup>9</sup> has recently collected forty-six cases from the literature in which group O blood caused reactions when injected into recipients of other groups. He reports a case of his own in which the group O serum of the donor agglutinated the recipient's A corpuscles in a dilution of 1:2,048. This is probably the highest titer on record.

As there are only three or four reports in which agglutinins in the donor's blood have been titrated, the following case seems worthy of consideration:

REPORT OF CASE

E. H., a woman, aged 25, had a medical induction of labor in the University Hospital June 6, 1936. Postpartum fever developed for which a blood transfusion was contemplated. The patient was found to belong to group AB. No donors of this type were available from the hospital donor list at that time, so her blood was cross-matched with that of a group O donor by the open slide technic of Vincent. No agglutination or hemolysis occurred in the mixture of the donor's corpuscles and the recipient's serum, but the donor's serum was seen to produce prompt agglutination and hemolysis of the recipient's cells. As this reaction was expected, citrated blood from the donor was transfused slowly into the patient by gravity. When 125 cc. of blood had been given, the patient complained of a feeling of constriction in the chest and

The practice of transfusing group O blood into individuals of other groups has become fairly common, although many writers have warned against it. Copher<sup>2</sup> stated that the use of the "universal donor" was dangerous. Levine and Mabec<sup>3</sup> studied the blood of one individual belonging to group O whose serum agglutinated the corpuscles of group A in a dilu-

severe shortness of breath. The administration of blood was promptly discontinued. She became intensely cyanotic and dyspneic. A marked chill occurred and the oral temperature

quate quantity of the antigen, which was found to be 0.1 cc. of the antigenic substance to 0.1 cc. of the undiluted serum.

All antigens had a marked tendency to absorb the agglutinins for sheep erythrocytes. However, the absorption by the kidney of the rabbit was noticeably less than that of the other antigens, particularly when smaller quantities of the antigen were used, while with larger quantities the nonspecific effect became more and more pronounced. The readiness with which the agglutinins were removed by beef erythrocytes was striking, particularly by comparison with the normal serum.

Serums of thirteen patients with infectious mononucleosis were absorbed repeatedly with the different antigens until maximum absorption was obtained. Serums of nine patients with mononucleosis were treated with the optimum quantities of antigens (0.05 and 0.1 cc. to 0.1 cc. of serum); 0.1 cc. of the beef cells and of beef heart removed promptly all agglutinins for sheep cells. Kaolin and kidney of the guinea-pig and of the rabbit removed between 50 to 75 per cent of the agglutinins. The average absorption was 50 per cent by kaolin, 61 per cent by the rabbit kidney, and 69 per cent by the guinea-pig kidney. Further absorptions did not remove any more of the antibody. The

of the guinea-pig kidney to remove them completely establishes the diagnosis of infectious mononucleosis, while removal of the sheep agglutinins with the guinea-pig kidney excludes mononucleosis. That the absorption of a serum with beef erythrocytes and of another sample of the same serum with the guinea-pig kidney offers a convenient method for the differential diagnosis of infectious mononucleosis will be illustrated by concrete examples.

#### TECHNIC OF THE DIFFERENTIAL TEST FOR INFECTIOUS MONONUCLEOSIS

##### ABSORPTION WITH BOILED BEEF ANTIGEN

Place in a test tube (85 by 16 mm.) 0.5 cc. of the thoroughly shaken 20 per cent suspension of boiled beef erythrocytes. Add 0.1 cc. of serum that has been heated for thirty minutes at 56 C. Shake and let stand at room temperature for one hour, shaking at fifteen minute intervals. Centrifugate at 1,500 revolutions for ten minutes. Remove the supernatant fluid with a capillary pipet. To a row of six tubes (75 by 12 mm.) add 0.25 cc. of physiologic solution of sodium chloride. To the first tube add 0.25 cc. of the absorbed serum. Mix and transfer 0.25 cc. to the second tube and so on. Discard 0.25 cc. from the last tube. The serum dilutions are 1:10, 1:20, 1:40 and so on. Add 0.1 cc. of a 2 per cent suspension of sheep cells. Shake well. Final dilutions of serum are 1:14, 1:28 and so on. Let stand at room temperature for two hours. Read.

##### ABSORPTION WITH BOILED GUINEA-PIG KIDNEY

Exactly the same procedure as before, using 0.5 cc. of the thoroughly shaken 20 per cent suspension. If it is necessary to begin with a dilution of 1:7, as may be the case in serums with titers below 1:112 (see case 31), add 0.2 cc. of serum to 1 cc. of the antigen suspension. For titration omit the physiologic solution of sodium chloride from the first tube, but in the other tubes, place the usual amount of 0.25 cc. From the absorbed serum, add 0.25 cc. to the first and to the second tube. Proceed as before. The final dilutions are 1:7, 1:14 and so on.

#### THE DIAGNOSTIC PROBLEMS IN INFECTIOUS MONONUCLEOSIS

It is stated frequently that infectious mononucleosis can be easily diagnosed from the results of the clinical and hematologic examinations. That is undoubtedly true in the majority of cases. However, my experience has taught me that not infrequently cases are encountered that present great diagnostic difficulties. The histories of the thirty cases that form the basis of this report confirm fully the opinions of those authors who emphasize the great variety of the manifestations of mononucleosis. Bernstein<sup>13</sup> enumerates twenty-nine conditions that may simulate mononucleosis. Among them he did not mention chronic lymphatic leukemia and monocytic leukemia, both of which may have to be differentiated from mononucleosis. He also failed to include eight conditions from which mononucleosis may have to be separated, as was the case in our series: acute appendicitis (case 1<sup>14</sup>), acute surgical conditions of the abdomen (other than appendicitis) (case 6), acute leukemia (cases 6 and 12), acute gastritis and hepatitis (case 12), agranulocytosis (case 2), acute meningitis and encephalitis (case 27).

I shall confine myself to a brief presentation of a few reports that will illustrate the value of the agglutination test and of the differential test for infectious mononucleosis.

The diagnostic difficulties in mononucleosis can be divided into five groups. To the first group belong the

Serum disease (three cases)...	91	...	97	...	..	100	...	100	..	95	..	..
Infectious mononucleosis (nine cases).....	342	100	100	...	..	99	100	...	69	..	61	.. 50

ability of the beef red cells to absorb the agglutinins for sheep cells from serums of patients with infectious mononucleosis was first reported by Bailey and Raffel<sup>11</sup> and was recently confirmed by Stuart and his associates.<sup>10d</sup> I observed the same phenomenon before the publication of their reports and have confirmed it since in every case of infectious mononucleosis. Beef heart tissue had the same effect as beef erythrocytes. However, in a few cases with very high titers, the beef heart removed the agglutinins for the sheep erythrocytes less efficiently than did the beef red cells.

Table 2 emphasizes the different behavior of the sheep agglutinins in the serum of normal persons and of persons with serum disease and with infectious mononucleosis with regard to the different antigens.

The failure of the guinea-pig kidney to remove the agglutinins for sheep erythrocytes from the serum of patients with infectious mononucleosis establishes that the heterophilic antibodies in that disease are not of the Forssman type. The readiness with which beef erythrocytes removed the antibodies in serum disease is contrasted with their failure to do it in normal serum. It is apparent that absorption with beef erythrocytes cannot be employed for the separation of infectious mononucleosis from serum disease but that absorption with guinea-pig kidney can clearly differentiate the two conditions. Removal of the agglutinins for the erythrocytes of sheep with beef erythrocytes and the failure

the relative height of the bottle to the pleural cavity. I have found that a bottle 20 cm. high and with a capacity of 700 cc. works very satisfactorily and will empty about once in thirty minutes when fluid is added by a moderately slow drip.

Clinical results have been excellent in all cases in which this apparatus has been used in conjunction with a closed type of thoracotomy.

Stuart Building.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

### SW-500 DELUXE MODEL SHORT WAVE GENERATOR ACCEPTABLE

Manufacturer: The Liebel-Flarsheim Company, Cincinnati.

The SW-500 DeLuxe Model Short Wave Generator is recommended for medical and surgical diathermy and hyperpyrexia. Application of the current may be made by the coil (electromagnetic field), pad or cuffs, and so-called spaced plates (electric field). The firm does not make any claims of advantages of one method of application over another, except that one method may be more convenient than another in some instances. Standard accessories supplied with the machine consist of supply cable, two 4 by 6 inch pad electrodes, two 6 by 8½ inch pad electrodes, two 9½ inch diameter plate electrodes, one 11 foot inductance cable, two 5 inch diameter plate electrodes, two adjustable supporting arms for plate electrodes, one set of felt spacers, one roll of elastic bandage and one set of cable retaining clips. Special applicators and surgical accessories are available as extras. The shipping weight of the unit is about 200 pounds.

De Luxe Model  
SW-500 Short  
Wave Generator  
(Liebel - Flarsheim).

High frequency currents of two wavelengths are available: one between 6 and 8 meters, the other between 18 and 20 meters. The power consumption is about 700 watts on 110 volt alternating current line.

The firm was asked to submit evidence substantiating the claims made for the heating ability of the unit. The firm engaged a reliable investigator to conduct the tests. He seated the subject in a comfortable position, with the legs spread apart. An incision was made in the thigh, approximately 6.3 inches from the knee, under aseptic conditions. A cannula was inserted in the quadriceps extensor muscle and in the subcutaneous tissue. Temperatures were read by three thermocouples of copper constantan, especially prepared to facilitate manipulation of them for taking readings at the cannula and on the surface of the skin. The thermocouples were removed from the field when the short wave current was passed through the thigh.

The voltage generated by the thermocouples was read by a type K potentiometer, manufactured by Leeds and Northrup Company. The thermocouples and potentiometer were calibrated in degrees Fahrenheit. Six observations were recorded.

A cotton face towel was held over the thigh on each side of the cannula. The under side of the thigh was uncovered, since the patient rested in a sitting position. Electrodes were 4.8 and 9.5 inches in diameter, and placed 1.4 inches from the skin surface. The 6 to 8 meter band was employed.

Readings were taken after every five minutes of application until a total of twenty minutes of application had been administered. The average time consumed during the temperature readings was three and one-half minutes. The cooling time temperature readings were also taken at ten and twenty minute intervals after the twenty minute application ceased. Oral temperatures were taken at the beginning and end of each treatment.

The time allowed between successive tests for the local temperature to drop to normal was sixty minutes.

The averages of six observations are recorded in table 1.

The manufacturer cooperated with the Council by submitting the short wave diathermy unit and the aforementioned data for consideration. The Council selected an independent investigator to test the unit. He conducted tests using the 6 to 8 meter band and employing "spaced-plate" electrodes. Three subjects were used in this test and a total of eight observations were recorded. The subject's treatment table had to be raised on four chairs before it was possible to apply the electrodes because the holders were too short when the subject was in a recumbent position. Two trocars placed in hard rubber cannulas were inserted into the thigh. One was inserted midway between Poupart's ligament and the knee and straight down into the depth of the muscular tissue until the instrument was at an approximate depth of 2 inches, or until the femur was encountered. The second was introduced as nearly parallel to the skin as possible and subcutaneously at an approximate depth of one-eighth inch. The trocars were removed, leaving the rubber cannulas in situ. Temperature measurements were then taken by means of thermocouples of the hypodermic needle type and introduced through the cannulas. The constant junction was immersed in ice enclosed in a quart vacuum bottle. The electromotive force due to the difference in temperature of the junctions was read in millivolts from the Leeds and Northrup portable potentiometer. The thermocouples were calibrated in degrees Fahrenheit against a Bureau of Standards certified thermometer. Initial temperatures were taken and then each subject was submitted to a twenty minute application of maximum current intensity consistent with skin comfort. At the end of this period, temperatures were again recorded until the

TABLE 1.—Average Temperatures of Six Observations

Deep Muscle		Subcutaneous		Oral Temp.	
Initial	Final	Initial	Final	Initial	Final
97.5	104.8	96.9	104.1	98.6	99.1

temperature began to drop. The highest temperature attained was recorded as the final temperature in each instance. Oral temperatures also were taken.

The "spaced-plate" electrodes, 4.8 inches in diameter, were placed laterally on the thigh equidistant from the cannulas. The distance from the skin to the electrode was from 1¼ to 2 inches.

Each reading in table 2 is the average of eight observations obtained on the spaced plates.

The results of the Liebel-Flarsheim tests indicate that the final temperatures in the muscle, subcutaneous tissues and mouth are somewhat higher than those obtained by the Council's investigator. It is to be remembered that, in the investigation carried out under the direction of the firm, the subject was placed in a sitting position, whereas in the Council's investigation the subject was in a recumbent position, or in the position in which patients are ordinarily treated.

A discussion of the reasons for the difference in results of the two investigations may be of interest. When the Council's

TABLE 2.—Average Temperatures in Eight Observations on Spaced Plates

subject was in a recumbent position, he was lying on a non-conducting and nonmetallic couch. A portion of the electrical energy, however, may have been absorbed by the mattress and the couch. On the other hand, with the firm's subject in a sitting position, there was less foreign material to absorb the energy, and furthermore precautions were taken to keep the other leg away from the inside electrode. In the thighs of the subjects investigated by the Council, the cannulas were inserted from 1 to 1½ inches proximal to the knee from those in the manufacturer's subject. The diameter of the "spaced-plate" electrode used by the Council's investigator was 4.8 inches, whereas the manufacturer's investigator used electrodes 4.8 and

1. The Council did not use these data as a basis for acceptance.

cells is on the borderline (1:56 and 1:112). It is in these cases that the new differential test for infectious mononucleosis becomes invaluable. Mononucleosis is excluded if the absorption with the guinea-pig kidney removes the agglutinins for sheep cells. Bailey and Raffel<sup>11</sup> suggested the absorption with beef erythrocytes as sufficient for differentiation, claiming that removal of the agglutinins for the sheep cells establishes the diagnosis of infectious mononucleosis. The results of the absorption experiments as presented in the first part of the paper demonstrated that in serum disease the agglutinins for sheep erythrocytes are readily removed by boiled beef erythrocytes. A considerable number of absorptions of serum from patients without infectious mononucleosis showed the ability of beef erythrocytes to remove agglutinins for sheep erythrocytes. If the absorption with beef erythrocytes were the only criterion, erroneous conclusions would result. Such errors are prevented by absorbing the serum with the guinea-pig kidney and with beef erythrocytes. Two cases will serve as illustrations:

*Lymphocytic angina with high (borderline) titers of heterophilic antibodies.* A boy, aged 7 years, was admitted with a

would have been erroneous, as was demonstrated in the differential test by the complete removal of the sheep agglutinins by the guinea-pig kidney.

Such cases, which are clinically and hematologically indistinguishable from infectious mononucleosis and are serologically negative as established by the agglutination test or by the differential test, are not infrequent. As I stated in my discussion of the paper of Downey and McKinlay,<sup>12</sup> there is a need for the separation of infectious mononucleosis as a serologically homogeneous group from the other group that is serologically negative. To avoid confusion it may be advisable to apply to the serologically negative group the old term "lymphocytic angina."

While in the foregoing cases with borderline titers the differential test helped to exclude infectious mononucleosis, in the fourth group of clinically and hematologically similar cases the differential test helps to establish the diagnosis of mononucleosis, as is illustrated by the following report:

*CASE 31.—Infectious mononucleosis with a low titer of heterophilic antibodies.* A man, aged 50, took ill in Florida in February 1936. He had enlarged inguinal and axillary lymph

sore throat and markedly enlarged lymph nodes. The spleen was moderately enlarged. The tonsils were covered with a membrane. The temperature was 102.4 F. The child looked very ill. Smears from the throat showed large numbers of Vincent's organisms. Diphtheria bacilli were absent. Examination revealed 7,200 white blood cells with 57 per cent lymphocytes and 1 per cent of so-called abnormal lymphocytes. The titer of sheep agglutinins was 1:112, which is the so-called borderline titer. The differential test was negative for infectious mononucleosis. The infection in the pharynx dominated the picture during the further course. The infection extended into the ethmoid and maxillary sinuses. The spleen continued to be enlarged. Repeated blood counts showed normal numbers of white blood cells and from 50 to 61 mononuclear cells, with from 1 to 3 per cent of so-called abnormal lymphocytes. The child improved gradually and left the hospital three weeks after admission.

A girl, aged 3 years, took ill with a sore throat and fever. The lymph nodes, particularly those of the neck, were enlarged and tender, the spleen and liver were enlarged. The differential smear showed 21 per cent neutrophilic leukocytes, 72 per cent lymphocytes, 5 per cent abnormal lymphocytes and 2 per cent monocytes. The test for heterophilic antibodies was 1:56+. The differential test was negative for infectious mononucleosis.

In both preceding cases the absorption with ox cells removed completely the agglutinins for sheep cells. To class them on that basis as infectious mononucleosis

nodes, fever and general malaise. A blood count early in March showed 17,000 white cells with 80 per cent lymphocytes. A diagnosis of infectious mononucleosis was considered but was not made with certainty. The patient improved and returned to his home, where it was considered advisable to establish the nature of his illness in Florida. On March 31 he had 7,000 white cells with 49 per cent mononuclear cells. The titer of the heterophilic antibodies was 1:56+. That alone was not sufficient to diagnose mononucleosis. However, the differential test (as shown in table 3) permitted a definite diagnosis of infectious mononucleosis. Its result was a complete absorption of the sheep agglutinins with beef cells and only partial absorption with the guinea-pig kidney.

The service that was rendered by the differential test in the last case is supported by another absorption shown in table 3. In a typical case of infectious mononucleosis (case 7) the titer of heterophilic antibodies was at its height, 1:896+. Thirty-eight days later the titer was below the diagnostic level for mononucleosis, 1:56+. However, the differential test showed the same result that is characteristic for infectious mononucleosis as at the height of the titer.

Another case (34) was seen recently in a physician with a marked leukopenia. His condition was first diagnosed as agranulocytosis and only later did the test permit the diagnosis of infectious mononucleosis. The

## OPIUM TRAFFIC IN THE UNITED STATES

As part of the international policy of controlling traffic in opium and other dangerous drugs, each nation signatory to the International Drug Conventions is supposed to prepare an annual report. The report of the United States of America for the year ended Dec. 31, 1935, has been prepared and published by the Bureau of Narcotics of the Treasury Department.<sup>1</sup> The number of nonmedical drug addicts in the United States is difficult to determine accurately, but, while formerly believed to approximate one person in every thousand of the population, recent surveys indicate that this figure no longer obtains in many sections of the country. In the nature of a further inquiry into the problem of addiction, the Bureau of Narcotics examined the records of 1,397 of the persons investigated in connection with violation of the narcotic laws as to their personal use of drugs. Of these, 946 were found to be addicted to some form of opium or coca derivative, the other 451 giving no evidence of addiction. Of the addicts, 757 were male and 159 female. The average age of the men was 41 and of the women 35. Seven hundred and seventy-five were white, eighty-eight oriental, seventy-eight colored and three American Indian, while in two instances the race was not reported. A striking feature was the educational background of these addicted violators. Five hundred and twenty had attended only grade school, 211 had reached high school but not college, and 153 had received some college or university training. These figures indicate a considerably higher percentage of moderately educated people than that existing among the general public.

The reasons given for drug addiction were of interest. In 486 instances "associations" were blamed; in 337, illness or injury was named as the responsible factor; other causes mentioned less frequently were indulgence or drink in fifty, mental strain or nerves in fourteen,

curiosity or experiment in ten, physical strain or overwork in six and deliberate addiction in one. The previous criminal records of the 946 addicts included 545 charges of felony, 468 misdemeanors and 1,887 violations of either federal or state narcotic laws. This is an extremely high criminal record; higher, in fact, than that found in any other group of lawbreakers.

The heaviest arrivals of raw opium in 1935 were in the Atlantic Coast area. There were fourteen seizures, three of which concerned fairly large quantities: 23, 19 and 17 Kg. The largest seizures of prepared opium were effected in the Pacific Coast area, almost all of which came from China and appeared to be mostly a blend of Chinese and Persian opium. More than twice as much smoking opium was seized in the United States in 1935 as in 1934, amounting in 1935 to 779 pounds. Morphine was seized in every area reviewed except Hawaii. The total quantity seized during the calendar year 1935 showed an increase of 27.5 per cent over that seized the previous year. The amount of heroin seized showed an increase of about 19 per cent over the previous year. The amount of cocaine taken, however, showed a decrease of 63 per cent as compared with that seized in 1934. The records as a whole contain substantial evidence in the form of labels, packages and detailed reports to show the existence of an extensively organized narcotic traffic in the Far East. The Opium Advisory Committee of the League of Nations has previously called attention to the extreme dangers resulting from this situation.

Closely allied with the opium traffic is the present situation with regard to Indian hemp, or marihuana. There is as yet no federal legislation penalizing traffic in this drug, and federal efforts are at present largely confined to restriction of imports and cooperation with those states or local bodies which have effective regulations.

The effectiveness of federal efforts to control the drug traffic, in cooperation with the League of Nations, is manifest by the amounts of drugs seized, the relatively smaller quantities in which they are transported and the high percentage of convictions obtained for violation of the laws. In this connection it is noteworthy that for every agent in the federal field service there are ten convicted narcotic violators in the federal penitentiaries. Only about 511 Kg. of narcotic drugs was seized in 1935, as compared with 3½ tons during the fiscal year 1931, when smuggling was rampant. Much smaller shipments are now found, combined with higher adulteration and increased retail price. The number of criminal violations detected rose from 4,742 in 1934 to 5,200 in 1935, while the convictions increased from 1,816 in 1934 to 2,065 in 1935. The two problems of greatest menace at the present time seem to be the rise in use of Indian hemp with inadequate control laws and the oversupply of narcotic drugs available in the Far East, which threatens to inundate the Western world.

cytes and I don't think any differential diagnostic difficulties exist between the blood picture of infectious mononucleosis and acute leukemia. The character of the nucleus of the large lymphatic cells is that of the mature lymphocyte with a trabeculated chromatin structure. It is definitely different from the leptochromatic nucleus of the immature lymphocyte. The basophilic cytoplasm of the cells which gradually leads to plasma cells is much more characteristic than the structure of the nucleus. I have seen a few cases of infectious mononucleosis in which the outstanding hematologic finding was an increase of the monocytes, not of the lymphatic cells, and in which there were also atypical monocytic cells of the so-called Rieder type. With the aid of the demonstration of the heterophilic antibodies, it is now possible to show that all these cases belong in the same group. Since there now exists such a reliable test as Dr. Davidsohn has pointed out, the next step will be to look for the infective agent, which I think will be found to be a virus.

DR. A. S. GIORDANO, South Bend, Ind.: Dr. Davidsohn should be congratulated on this work, which began in 1927 when he was primarily interested in the determination of type of heterophile antibodies. The differential test that he has presented is of great aid to the clinical pathologist, who is frequently confronted with atypical cases which he cannot hematologically classify definitely in any particular group. The aid of the heterophile antibody and the other differential tests suggested by Dr. Davidsohn definitely establish the diagnosis. I wish to mention two cases from my experience that illustrate the value of these tests. The first patient was a girl, aged 18, sent home from college with a diagnosis of agranulocytic angina. Her white blood cell count was 1,200 per cubic millimeter. The lymphocytes ranged from 70 to 78 per cent. Some of the cells appeared immature and it was possible that the condition might be either leukemia or infectious mononucleosis, since there were only 8 per cent polymorphonuclear cells and the rest were monocytes. The heterophile antibody agglutination revealed an agglutination above 1:140. This quickly established a diagnosis, and a good prognosis was given to the father, who was a physician. The second patient was a child, aged 8 years. The pediatrician in the case found fever, an enlarged spleen, enlarged nodes and a white cell count of 20,000, with 82 per cent lymphocytes. The clinical diagnosis of acute lymphatic leukemia was made. In this case, too, the heterophile antibody quickly established the correct diagnosis of acute infectious mononucleosis. I can agree with everything that Dr. Davidsohn has said, but for the present it cannot be said definitely that infectious mononucleosis is really a clinical entity, since it can be mistaken for many other different clinical pictures. These cases can be classified serologically into one group and for the others one must wait until the etiology of the disease has been established. If anything has been learned from experience in other infectious diseases, it is known that in undulant fever the blood may have no agglutinins at all and some have low titers. The low titers in infectious mononucleosis are easily disposed of with the kidney absorption test, illustrating the point that low titers may be of great diagnostic significance.

DR. ISRAEL DAVIDSOHN, Chicago: My experience has been similar to Dr. Jaffé's. In none of my cases did I have any serious difficulty in differentiating the condition from acute leukemia. However, I was told only a few days ago by Dr. Hal Downey, an authority on the blood in infectious mononucleosis, that in his experience in about 5 per cent of the cases it is difficult to diagnose infectious mononucleosis from the blood examination alone. The differentiation from chronic leukemia is sometimes quite difficult, just as Dr. Jaffé mentioned. Furthermore, why not use a test that makes it possible to make the diagnosis so much easier than it is with the fine hematologic differentiation? I fully agree with Dr. Giordano and I want to state it once more that the serologic examination establishes merely a serologic group of infectious mononucleosis but does not permit any further conclusions. I stated last year while discussing the papers of Dr. McKinlay and Drs. Downey and Stasney at the meeting of the American Medical Association that there is reason to assume that there exist two types of infectious mononucleosis: the seropositive and the seronegative type.

## Clinical Notes, Suggestions and New Instruments

### THE FREQUENCY OF AIR UNDER THE DIAPHRAGM IN PERFORATED GASTRIC AND DUODENAL ULCER

REPORT OF FORTY-TWO CONSECUTIVE CASES

SYDNEY E. JOHNSON, M.D., LOUISVILLE, KY.

Roentgenographic demonstration of air under the diaphragm in cases of perforated peptic ulcer has been reported by many authors and is mentioned briefly in all modern textbooks on roentgen interpretation. All authors agree that demonstration of spontaneous pneumoperitoneum is pathognomonic of perforation, but the reader is left in considerable doubt as to the frequency with which air can be demonstrated in such cases. Since the finding of air is pathognomonic, the value of this sign depends on the percentage of cases in which the sign can be elicited. With the idea of getting more definite information on this question, I have examined the charts of all patients admitted to the Louisville City Hospital during the past five years who have had an admission diagnosis of perforated peptic ulcer, seventy-six cases in all. Thirty cases must be eliminated because there was no x-ray examination. The remaining forty-six cases were examined roentgenologically; thirty-five gave the positive finding of air under the diaphragm and eleven were negative.

Of the eleven negative cases one must be eliminated because it was found at operation that the ulcer had not perforated. Three others are excluded because there is no operative or necropsy confirmation of the clinical diagnosis. The remaining seven patients in the negative (x-ray) group were proved by operation to have perforated ulcers.

All the thirty-five patients in the positive group were proved by operation or necropsy to have perforated ulcers.

In considering the available data in both the negative and the positive cases the following facts would appear to be of greatest importance: (1) the time elapsed between the perforation and the x-ray examination, (2) the size of the opening, and (3) the amount of scarring at the site of the ulcer. The site of the ulcer, the age of the patient and the sex may have some effect, but this is not indicated in our small group of cases.

The time elapsing between perforation and the roentgen examination is undoubtedly determinable with a high degree of accuracy, assuming that perforation coincides with the sudden attack of severe pain. Practically all the patients in our group gave the exact hour of the attack. The time between the attack and the roentgen examination in the thirty-five patients who showed air under the diaphragm ranged from one to thirty-six hours and averaged eight and one-half hours. The time in the seven patients who had perforated ulcers but no air averaged thirty-six hours and ranged from one hour to five days. In the roentgen-positive group the time was under ten hours in twenty-two patients and under twenty hours in all but four. In two patients of this group the time was thirty-six hours. Both of these patients had large perforations, the opening in one admitting the index finger of the operator.

With regard to the size of the perforations, the records are incomplete. The size is recorded in twelve of the thirty-five patients in the roentgen-positive group, with a range from 2 to 15 mm. and an average of 6.5 mm. In two of the roentgen-negative group the size is recorded as one-fourth inch and 4 mm., respectively.

There is no record as to the amount of scarring at the site of perforation, but this may bear some relation to the chronicity of ulcer symptoms. The duration of ulcer symptoms in the roentgen-negative group averages one and one-half months, with extreme limits of from three days to five years. In the roentgen-positive group the histories average three and one-half years, with extremes of from one month to thirty years. All the patients with very long histories gave positive roentgen signs. This may have a definite relationship to the amount of induration at the site of the ulcer.

From the University of Louisville School of Medicine.

being who died following a cholecystectomy with the typical syndrome of hyperpyrexia of Heyd's group 1. Pytel<sup>5</sup> stated that he was able to reproduce the hepatorenal syndrome in rabbits by ligation of the hepatic artery, by subcapsular traumatization of the liver, by intraperitoneal and intravenous injection of liver extracts prepared from livers of animals in which the syndrome was produced, and by the injection of blood from such animals into normal animals.

A number of theories have been advanced to explain the liver death. Helwig, Orr and Schutz believe that an unknown powerful toxic substance is generated in the necrotic liver tissue and that this toxin exerts a specific effect on the renal tissue, causing degeneration and necrosis of the epithelium of the convoluted tubules. Boyce and McFetridge, as well as Pytel, do not believe in a specific toxic effect on the kidney but regard the alterations in the renal epithelium as the result of an overtaxed normal physiologic process, the excretion of foreign proteins by the convoluted tubules. The significance of the hepatorenal syndrome lies in the fact that every case of disease of the biliary passages is associated, as established by Reimann and by Graham, with more or less hepatic involvement. Unfortunately, exact tests of the liver function have not been evolved. Wilensky suggested that the renal function might be regarded as the reflection of the hepatic function. Among measures that may render an operative intervention on the liver or the bile tracts safer, the following are recommended: careful tests of the hepatic and renal functions, administration of dextrose and fluids in large amounts, administration of calcium, lessening the amount of trauma and exposure of the liver in the course of the operation, abstaining from suturing the fossa of the gallbladder, and the proper selection of an anesthetic.

## Current Comment

### WILLIAM ALLEN PUSEY HONORED

The January 1937 issue of the *Archives of Dermatology and Syphilology* is a special number dedicated to Dr. William Allen Pusey. The honorary volume was authorized by the Board of Trustees of the American Medical Association in recognition of the founding of the publication by Dr. William Allen Pusey and of his devoted service to it since that time. All the contributors have been associated with Dr. Pusey in various activities. In addition to tributes to Dr. Pusey as a leader in organized medicine by Dr. Olin West, as editor by Dr. Morris Fishbein, as educator by Dr. D. J. Davis and as a historian and litterateur by Dr. James B. Herrick, there is a statement on Dr. Pusey as a citizen by Rufus C. Dawes. Next come articles on Dr. Pusey's contributions to cutaneous medicine and syphilis by Dr. C. Guy Lane, and a biographic study by his assistant, Dr. Herbert Rattner. The remainder

of the volume is devoted to articles by associates and colleagues of Dr. Pusey. These articles concern various scientific dermatologic subjects. Especially important is an extensive contribution by Dr. Leonard F. Weber on external causes of dermatitis, which constitutes a complete listing of chemical substances, plant substances and other materials which have from time to time been reported as irritant causes of dermatitis. Dr. Pusey retires as editor of the *Archives of Dermatology and Syphilology* with the current issue. The new editor, Dr. Howard Fox, concludes the special issue with an editorial rendering tribute to the manner in which the *Archives* has been brought by Dr. Pusey to the leading place which it occupies in the dermatologic literature of the world.

### STAINS FOR TISSUE OF THE NERVOUS SYSTEM

The methylene blue staining method introduced by Ehrlich in 1885 contributed more than any other staining method (Weigert's hematoxylin, silver nitrate) to our knowledge of the anatomy of the peripheral and sympathetic nervous system. During the last two decades Russian investigators have perfected this method to such an extent that it has become possible to follow up by mere dissection the distribution of the sympathetic nerve fibers over large areas in an animal's organ without previous fixation, embedding and sectioning. It has become possible to stain areas termed by Worobiew macromicroscopic, that is, intermediary areas as it were, bordering on gross and microscopic fields.<sup>1</sup> After careful and critical analysis of the factors that constitute the rationale of the methylene blue staining method, Schabadasch<sup>2</sup> has succeeded in perfecting the method and has made it possible to follow up not only the macromicroscopic areas but also microscopic fields under magnifications as high as 1,200. He calls his method spatial microscopy (raummikroskopie). Basing his investigations on more than 1,600 staining experiments and a critical study of the literature, he concludes that successful staining with methylene blue is due not to the excess or presence of oxygen or to alkalosis but to a prevalence of hydrogen and acidity; that the carbohydrates are the chief source of hydrogen, without which the staining with methylene blue cannot succeed. This dye causes a chain of chemical phenomena in the tissues—transformation of aldehydes into acids, splitting of the carbohydrates and combustion of organic acids. By adding to the solutions of methylene blue chemicals such as dextrose, phenol, hedonal, magnesium chloride and magnesium bromide, Schabadasch has succeeded in obtaining excellent results in cases in which staining with the classic method ordinarily fails. The brilliant success of the modifications of Ehrlich's method and the correctness of the premises on which Schabadasch has based them he demonstrates in twenty-

rapidly rose to 106.2 F. The pulse rate was 140 and the respiratory rate 44 per minute. Two hours after the transfusion the recipient's blood serum was found to be tinged with hemoglobin, and the van den Bergh reaction was 2.0 (biphasic). There was no hemoglobinuria or oliguria. The symptoms persisted only a few hours and by the next day she felt well. The postpartum fever had disappeared and the van den Bergh reaction on the blood plasma was 0.5 (indirect). Recovery from hemolytic reaction and from postpartum fever was complete and prompt.

#### STUDY OF DONOR'S SERUM

The donor, a healthy man, aged 27, had never received blood in a transfusion and had had no severe illnesses, either recent or remote. His blood was retyped and belonged to group O. The recipient's blood was checked and established as group AB.

Tests for hemolysis and agglutination were set up in 8 mm. test tubes. Five-tenths cubic centimeter of a 0.25 per cent suspension of corpuscles in physiologic solution of sodium chloride was added to each tube containing 0.5 cc. of various dilutions of the donor's serum in physiologic solution of sodium chloride. The mixtures were well shaken and read after one hour at 37 C. The results are included in the accompanying table. (Agglutination was observed but not recorded with the cells of Henry and Randall.) It can be concluded from this that the  $\alpha$  agglutinin of the donor was potent in a dilution of 1:80 and the corresponding hemolysin in a dilution of 1:12 to 1:20. The  $\beta$  agglutinin was active only in a dilution of 1:12.

#### COMMENT

It is one thing to state that a certain serum contains an agglutinin which causes agglutination of a 0.25 per cent suspension of A corpuscles in a test tube, well shaken, at 37 C. in the course of one hour. However, it is almost unpredictable how much agglutination and hemolysis that same serum will cause when injected at the rate of 10 cc. per minute into the median basilic vein of a group AB recipient. It is obvious that near the site of injection the antibodies will be more concentrated. The blood corpuscles and, perhaps, the fixed tissues of the recipient will absorb a certain amount of agglutinins. The amount of free hemoglobin in the blood stream and the amount of agglutination required to produce a serious clinical reaction in man is unknown.

Nevertheless, it may be of interest to use the physical constants that are known in this case to calculate what would take place if the injected agglutinins and hemolysins were not absorbed. The recipient weighed 68 Kg. If one assumes that 8.8 per cent of her body weight was blood,<sup>10</sup> the blood weight was 5,456 Gm. The hemoglobin was approximately 80 per cent. No hematocrit determination was made, but it may be assumed that 68 per cent, or 3,710 Gm., of the blood was serum. If the donor's blood was normal, 75 cc. of serum was injected. If an average value of 1.050 is taken for the specific gravity, the weight of serum injected was 78.75 Gm. If one ignores the possible effects of dilution of serum with corpuscles, the donor's serum should have attained a dilution in the recipient's serum of 1:47. According to the tests in vitro, the 75 cc. of donor's serum should have agglutinated all the recipient's corpuscles in an hour. This obviously did not take place, so absorption must have immobilized most of the hemolysins and agglutinins injected.

The only safe statement to make from these data is that the injection of 125 cc. of blood from this group O donor into an individual of group AB is dangerous. The same also applies to a group A recipient. A group B recipient could probably safely receive this donor's blood.

#### SUMMARY

The injection of 125 cc. of blood from a certain group O donor into a group AB recipient, who was only slightly anemic, produced a severe reaction with evidence of hemolysis in vivo. The donor's blood was found to contain an  $\alpha$  agglutinin active in a dilution of 1:80 and a corresponding hemolysin active in a dilution of from 1:12 to 1:20. The  $\beta$  agglutinin was potent only in a dilution of 1:12.

### TIDAL IRRIGATION OF EMPYEMA CAVITIES WITH SIMPLIFIED APPARATUS

H. B. MORTON, M.D., LINCOLN, NEB.

There appeared in the December 1935 issue of *International Clinics*<sup>1</sup> an excellent article on the treatment of acute empyema in which attention was directed to the value of "tidal irrigation" in promoting early complete closure of an empyema cavity.

The procedure was accomplished by a series of two or more bottles so arranged as to hydrostatics that alternate irrigation and mild suction would be applied to the pleural cavity. The principle seemed excellent, but the recommended apparatus seemed quite intricate.

The apparatus here described is offered as a simplified method of carrying out tidal irrigations and has been found to function in an excellent manner.

Irrigating fluid is supplied from a reservoir through a drip, the flow of which is regulated by a screw clamp. As the fluid drips into the irrigating system, it flows into the pleural cavity and into the bottle as illustrated. This bottle carries an open end inverted U tube, which acts as a siphon when the bottle is

Simplified apparatus for tidal irrigation of empyema cavities: A, 700 cc. flask; B, Hoffman clamp; C, drip; D, T tube; E, visible connector; F, bottle and siphon (shown also in inset); G, catheter into pleural cavity; H, gallon receptor.

full. The height of the bottle is such that the upper fluid level will be about 3 or 4 cm. above the level of the empyema cavity while the lower fluid level will be about the same distance below the cavity. A minute vent in the top of the bottle prevents the siphon from acting until the fluid reaches the higher level in the bottle. By this arrangement the pleural cavity is alternately irrigated at a slight positive pressure and aspirated at a slight negative pressure. During both of these processes there is a "tidal" to and fro motion of the fluid in and out of the chest cavity synchronous with respiration. The latter action tends to keep the irrigating system open and break up fibrin particles.

With this apparatus in operation one is able to see pus and fibrin propelled along the tubing toward the bottle with each respiratory excursion. When the fluid nears the upper level of the bottle the solution in the tubing clears, showing that irrigation is taking place. When the fluid is at a low level the solution becomes quite turbid, as evidence that suction is emptying the pleural cavity.

An adjustment between the relative amounts of suction and irrigation or the pressure in the system can be regulated by

1. Hart, Deryl: *Treatment of Acute Empyema*, *Internat. Clin.* 4: 184 (Dec.) 1935.

the speakers. Of sixty-two years in the practice of medicine, Dr. MacLaren has spent forty-nine in Port Huron. He is 87 years of age. According to the announcement, he served the community as police commissioner in 1900 and later as health commissioner. He graduated from the Long Island College of Medicine in 1876.

**State Society Night.**—The Monroe County Medical Society observed a "state society night" at its meeting at the Monroe Country Club, December 17. The following program was presented:

Dr. Louis Fernald Foster, Bay City, secretary of the Michigan State Medical Society, Greater County Society Activity and Organization.

Dr. Paul R. Urmston, Bay City, chairman of the council of the state society.

Mr. William J. Burns, Lansing, executive secretary of the state society, What Your State Society Is Doing for You.

In a discussion of "What the Next Legislature Means to the Practitioner of Medicine," Dr. Howard H. Cummings, Ann Arbor, councilor of the fourteenth district, considered the basic science bill; Dr. Philip A. Riley, Jackson, vice speaker of the house of delegates of the state society, the physician's responsibility, and Dr. Leo G. Christian, Lansing, chairman of the state legislative committee, other legislative issues of importance to the physician.

### MINNESOTA

**Society News.**—The Red River Valley Medical Society devoted its meeting, December 8, to a discussion of medical economics; the speakers were Drs. William W. Will, Bertha, president of the state medical association; Willard L. Burnap, Fergus Falls, councilor of the eighth district, and Mr. R. R. Rosell, St. Paul, assistant to the secretary of the state association, Dr. Edward A. Meyerding. —Dr. William D. Beadie, medical director and superintendent of Mineral Springs Sanatorium, Cannon Falls, was the guest speaker before the Rice County Medical Society in Faribault, December 9.

**Fifty Years of Service.**—Dr. Jacob C. Rothenburg, Springfield, was guest of honor at a banquet, December 15, given by the Springfield Booster Club in recognition of his completion of fifty years in the practice of medicine. Speakers included Drs. Walter G. Nuessle, Springfield, and George B. Weiser, New Ulm. Mr. Fred W. Johnson, president and founder of the Brown County Historical Association, presented an account of the early physicians of the county. Dr. Rothenburg is 76 years of age and a graduate of the University of Michigan Department of Medicine and Surgery, Ann Arbor, class of 1885.

**Director of Student Health Service Appointed.**—Dr. Ruth E. Boynton, associate professor of preventive medicine and public health, University of Minnesota Medical School, Minneapolis, has been appointed director of the student health service of the university. Dr. Boynton succeeds Dr. Harold S. Diehl, who was appointed dean. She graduated from Minnesota in 1921 and became director of the division of child hygiene, state board of health, in 1923. This position she held until 1927, when she went to the University of Chicago Medical School as assistant clinical professor of medicine; she was also connected with the student health service there. In 1928 she was appointed to the associate professorship at Minnesota.

### MISSOURI

**Medicolegal Committee.**—The St. Louis Medical Society has appointed a medicolegal committee with the following members: Drs. Max J. Bierman, chairman, and Paul R. Nemours and Edward J. Helbing. The committee is appealing not only to members of the state association in St. Louis but to physicians throughout the state for funds to finance its activities.

**Lectures on Cancer.**—At a meeting of the Buchanan County Medical Society in St. Joseph, January 6, Drs. Ferdinand C. Helwig and Charles Edgar Virden, Kansas City, discussed "Diagnosis and Treatment of Cancer of the Rectum" and "Roentgen-Ray Diagnosis of Diseases of the Colon" respectively. —The St. Charles County Medical Society will be addressed February 2 by Drs. Edwin C. Ernst and Warren R. Rainey, St. Louis, on "Roentgen-Ray Aid in the Diagnosis and Treatment of Diseases of the Colon" and "Cancer of the Rectum" respectively. These lectures are presented under the auspices of the cancer committee of the state medical association.

**Society News.**—Dr. Harry J. Corper, Denver, addressed the Kansas City Academy of Medicine, December 18, on "Recent Advances in the Pathology of Tuberculosis." —At a meeting of the Adair-Knox-Schuyler-Sullivan Counties Medical Society in Kirksville, December 4, Dr. Edward S. Smith, Kirksville, discussed dysentery. —The Dallas-Hickory-Polk Counties Medi-

cal Society was addressed in Buffalo December 1 by Drs. Francis T. H'Doubler, Springfield, on "Diagnosis, Differential Diagnosis and Treatment of Gallbladder Disease and Its Associated Biliary System"; Elmer E. Glenn, Springfield, "The Heart Patient a Surgical Risk," and Horace G. Savage, Warsaw, "True Bronchial Asthma." —Jacques J. Bronfenbrenner, Dr. P.H., professor of bacteriology and immunology, Washington University School of Medicine, addressed the Trudeau Club of St. Louis, January 7, on "Immunology in Tuberculosis."

### NEBRASKA

**Practitioners Honored for Fifty Years of Practice.**—

Dr. John W. King, Hartington, was the guest of honor at a dinner given by the Cedar-Dakota-Dixon-Thurston-Wayne Counties Medical Society at Wayne, December 10, in celebration of his completion of fifty years of medical practice. Dr. Charles T. Ingham, Wayne, was toastmaster and Dr. Lucien Stark, Norfolk, was the principal speaker. The society presented a clock to Dr. and Mrs. King. Dr. King graduated from the Detroit College of Medicine in 1886. He has practiced in Hartington for forty-five years. —Dr. Allen H. Hostetter, Douglas, received a service award at a joint banquet of the Nebraska City Rotary Club and the Otoe County Medical Society, November 18. Dr. Benjamin F. Bailey, Lincoln, was the principal speaker. Dr. Hostetter is a native of Indiana and a graduate of Rush Medical College, Chicago, class of 1886.

### NEW HAMPSHIRE

**New State Health Officer.**—Dr. Travis P. Burroughs, health officer of Concord, has been appointed secretary of the state board of health to succeed the late Dr. Charles Duncan. Dr. Burroughs is a native of Missouri and 41 years old. He graduated from the University of Missouri in 1917 and from Harvard University Medical School in 1925. He served an internship at Albany Hospital, Albany, N. Y., and lived in several New York towns before coming to Concord.

### NEW YORK

**Hundredth Anniversary of County Society.**—The Chemung County Medical Society recently celebrated the one hundredth anniversary of its founding with a dinner meeting at the Hotel Mark Twain, Elmira. Dr. Floyd Winslow, Rochester, president of the Medical Society of the State of New York, was a guest, discussing social problems confronting the medical profession. Dr. Arthur W. Booth, Elmira, a trustee of the American Medical Association, reviewed the history of the society; Dr. Ross G. Loop described methods and treatments used by physicians during the past hundred years, and Dr. Anna M. Stuart told of women physicians in the society's history. Dr. Reeve B. Howland displayed an exhibit of instruments and pictures of former physicians of the county. The program closed with a playlet written by Dr. Booth, "The Doctor's Dream," and played by Drs. Deborah M. H. Wyttenbach, Charles L. Stevens, Joseph S. Lewis, LaRue Colegrove, Lawrence L. Hobler and Reeve Scott Howland.

### New York City

**Laboratory for Diagnosis of Tropical Diseases.**—The department of hospitals has established at Bellevue Hospital a laboratory for tropical and subtropical diseases, which have been found to be common especially among the foreign population of New York. Dr. Douglas Symmers, general director of laboratories of the department of hospitals, will have supervision of the laboratory and in immediate charge will be Drs. Harry Most and Amanda Hoff. The laboratory is prepared to study peculiar forms of malaria, hookworm and other intestinal parasites, leprosy, yaws, sprue, Delhi boil, Maduro foot, Bilharzia and related fluke diseases, beriberi, Peruvian wart disease, amebic and bacillary dysentery and trachoma.

**Symposium on Care of the Mentally Ill.**—The division of psychiatry of the department of hospitals held a symposium on care of the mentally ill in the psychiatry building at Bellevue Hospital, December 16. Representatives of social, legal and medical agencies of the state and city attended the symposium, the purpose of which was to promote cooperation between the agencies and the city's hospital service. On the program were Drs. Sigismund S. Goldwater, commissioner of hospitals; Samuel W. Hamilton, White Plains, N. Y., who discussed "Psychiatric Care in New York City"; Karl M. Bowman, director of the division of psychiatry at Bellevue; and Mr. Stanley P. Davies, general director of the Charity Organization Society, "Psychiatry from the Standpoint of Social Agencies."

9.5 inches in diameter. The foregoing citations may account for some of the differences in the temperatures between the two investigations.

However, the Council's results indicate that the unit meets the minimum requirements; that is, what can be expected from the application of conventional diathermy—with a metal electrode on the medial aspect of the thigh and another metal electrode on the lateral aspect of the thigh—the method of application that has been adopted as a minimum standard of acceptance.<sup>2</sup>

The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is much less than with conventional diathermy.

The machine was installed in a clinic acceptable to the Council and operated under actual clinical conditions for three months. It was reported as giving satisfactory service. In view of the favorable report based on the data obtained by the Council's investigator, using "spaced plates," applied laterally, the Council on Physical Therapy voted to include the SW-500 DeLuxe Model Short Wave Generator in its list of accepted devices.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

#### RED STAR FRESH COMPRESSED YEAST

*Manufacturer.*—Red Star Yeast and Products Company, Milwaukee.

*Description.*—Fresh compressed yeast with added starch and vegetable oil.

*Manufacture.*—A mash of small grains, composed principally of cooked corn, barley malt and barley malt sprouts, is maintained at an optimum peptonization temperature and later saccharification temperature until the starch has been converted to soluble carbohydrates. Lactobacilli are introduced and allowed to grow until a desired acidity is reached. The mash is held at pasteurization temperature for several hours and filtered. The filtrate is treated with seed yeast prepared from pure culture yeast. The fermentation proceeds under forced aeration with filtered air and temperature control. The yeast growth is separated by centrifugation, cooled, mixed with starch, collected on filter cloths in filter presses, packed in 75 pound wax-paper lined boxes, and refrigerated. The bulk yeast is shipped under refrigeration to branch warehouses located in the important market centers, where the yeast is mixed with a small amount of water and refined vegetable oil, cut down to desired commercial sizes and wrapped for distribution. Stock not to exceed two days' requirements is maintained at the branches and sub-branches to assure freshness. Unsold yeast in retail stores is regularly replaced with fresh stock without charge.

*Analysis* (submitted by manufacturer).—Moisture 68.0%, total solids 32.0%, ash 1.8%, fat (ether extract) 0.3%, protein (N  $\times$  6.25) 12.0%, unsaponifiable matter (largely vegetable oil) 0.1%, starch (foil wrapped package) 9.0% and total carbohydrates (by difference) 17.9%.

*Calories.*—1.2 per gram; 34 per ounce.

*Vitamins.*—One cake (19 Gm.) contains approximately 19 International Units of vitamin B<sub>1</sub> and 38 Sherman Units of vitamin G.

*Claims of Manufacturer.*—A rich source of vitamins B and G. It is mildly laxative to many persons.

- (1) SEXTON BRAND STRAWBERRIES, JUICE PACKED
- (2) SEXTON BRAND RED RASPBERRIES, JUICE PACKED
- (3) SEXTON BRAND LOGANBERRIES, JUICE PACKED
- (4) SEXTON BRAND BLACKBERRIES, JUICE PACKED

*Manufacturer.*—John Sexton & Company, Chicago.

*Description.*—(1) Canned strawberries, packed in juice. (2) Canned red raspberries, packed in juice. (3) Canned loganberries, packed in juice. (4) Canned blackberries, packed in juice.

*Manufacture.*—Berries picked at the proper stage of ripeness are inspected (strawberries hulled), graded for quality and size, automatically filled into cans and weighed. Cans filled with juice (extracted from ripe fruit prepared similarly, heated, pressed and filtered) are exhausted, sealed and processed.

*Analyses* (submitted by manufacturer).—(Analyses of entire contents including liquid):

	(1)	(2)	(3)	(4)
Moisture .....	87.5%	84.9%	86.7%	88.0%
Total solids .....	12.5	15.1	13.3	12.0
Ash .....	0.5	0.4	4.4	0.5
Fat (ether extract) .....	trace	0.1	0.1	0.1
Protein (N $\times$ 6.25) .....	0.6	0.7	0.8	0.8
Crude fiber .....	0.7	2.5	2.1	3.5
Carbohydrates other than crude fiber (by difference) .....	10.7	11.4	9.9	7.1

*Calories.*—(1) 0.45 per gram, 13 per ounce; (2) 0.49 per gram, 14 per ounce; (3) 0.43 per gram, 12 per ounce; (4) 0.32 per gram, 9 per ounce.

*Claims of Manufacturer.*—For diets in which sweetened fruit is proscribed.

#### (1) CONGRESS BRAND CRYSTAL WHITE SYRUP

#### (2) K. C. BRAND GOLDEN SYRUP

*Distributor.*—Kansas City Wholesale Grocery, Kansas City, Mo.

*Packer.*—Union Starch and Refining Company, Granite City, Ill.

*Description.*—(1) A table syrup; corn syrup sweetened with sucrose; flavored with vanilla extract. The same as Pennant Crystal White Syrup (THE JOURNAL, Jan. 30, 1932, p. 402).

(2) A table syrup; corn syrup flavored with refiners' syrup. The same as Pennant Golden Table Syrup (THE JOURNAL, Jan. 30, 1932, p. 403).

#### JACOB MUSHROOMS "FILLET'S"

*Manufacturer.*—Grocery Products Manufacturing Corp., West Chester, Pa.

*Description.*—Hothouse mushrooms cut in "fillet" like slices.

*Manufacture, Analysis and Calories.*—Essentially the same as Jacob Mushrooms Broth, Fancy Buttons, Sliced, Sliced Stems and Pieces (THE JOURNAL, Sept. 15, 1934, p. 838).

#### BADGER BRAND EVAPORATED MILK SUNCREST BRAND EVAPORATED MILK

*Manufacturer.*—Consolidated Badger Cooperative, Shawano, Wis., subsidiary of Land O'Lakes Creameries, Inc., Minneapolis.

*Description.*—Unsweetened evaporated milk.

*Manufacture.*—The procedure of evaporation and canning, and the analysis are essentially the same as for Land O'Lakes Unsweetened Evaporated Milk (THE JOURNAL, July 28, 1934, p. 260).

#### KEYCO BRAND PINEAPPLE JUICE

*Distributor.*—Keystone Wholesale Grocery Company, Reading, Pa.

*Packer.*—Hawaiian Pineapple Company, Ltd., San Francisco.

*Description.*—Canned Hawaiian pineapple juice retaining in high degree the natural vitamin content; the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p. 1769).

2. Mortimer, Bernard, and Osborne, S. L.: Tissue Heating by Short Wave Diathermy, J. A. M. A. 104:1413 (April 30) 1935.

## TEXAS

**Hospital News.**—Dr. Barton W. Dorbandt, assistant superintendent of the San Antonio State Hospital, has been appointed superintendent of the Wichita Falls State Hospital. He succeeds Dr. Charles W. Castner, who has been made head of all state cleemosynary institutions, according to newspaper reports. —The Thompson Sanatorium, Kerrville, has been sold to the state to be used as a state hospital for Negroes with tuberculosis.

**Society News.**—Drs. Milford O. Rouse and Curtice Rosser, Dallas, addressed the Brown-Mills County Medical Society, December 14, on "Diagnosis and Treatment of Constipation, Irritable Colon, Fermentative Diarrhea and Nervous Indigestion" and "Management of Minor Anorectal Conditions" respectively. —The North Texas Medical Association held its semiannual meeting in Dallas December 8-9. Among the speakers were Drs. Leroy D. Long, Oklahoma City, on diseases of the thyroid gland, and Oliver C. Melson, Little Rock, Ark., on diagnosis of blood dyscrasias. —Dr. John T. Moore, Houston, addressed the Liberty-Chambers Counties Medical Society, December 10, on "Carcinoma of the Cervix."

**Graduate Assembly in San Antonio.**—The fifth annual clinical meeting of the International Postgraduate Medical Assembly of Southwest Texas will be held in San Antonio, January 26-28, with headquarters at the St. Anthony Hotel. The activities will include general meetings morning and afternoon, section luncheon meetings and evening assemblies the first two days. The guest speakers will be Drs. Albert M. Snell, Rochester, Minn., medicine; Frederick J. Taussig, St. Louis, obstetrics and gynecology; Samuel W. Becker, Chicago, dermatology; Manuel Martinez Baez, Mexico City, medicine; John M. T. Finney, Baltimore, surgery; Fremont A. Chandler, Chicago, orthopedic surgery; Albert C. Furstenberg, Ann Arbor, Mich., otolaryngology; Julius H. Hess, Chicago, pediatrics; Cecil S. O'Brien, Iowa City; William C. Quinby, Boston, urology; Alfonso Ortiz Tircedo, Mexico City, orthopedic surgery, and Ignacio Gonzales Guzmán, Mexico City.

## UTAH

**State Mental Hygiene Meeting.**—Dr. Alfred A. Robinson, Ogden, was elected president of the Utah State Society for Mental Hygiene at a meeting in Salt Lake City December 18. The guest speaker at the meeting was Dr. Charles A. Rymer, assistant director of the Colorado Psychopathic Hospital and assistant professor of psychiatry, University of Colorado School of Medicine, Denver.

## VIRGINIA

**Society News.**—Dr. Edwin C. Hamblen, Durham, N. C., addressed the Halifax County Medical Society, December 11, on "Treatment of Functional Uterine Bleeding." —Dr. Nelson B. Sackett, New York, addressed the Norfolk County Medical Society, November 30, on carcinoma of the uterus.

**Special Committees on Pneumonia and Syphilis.**—The president of the Medical Society of Virginia, Dr. James Morrison Hutcheson, Richmond, has announced the appointment of two new committees, among others. A pneumonia commission to investigate the incidence and types of the disease in Virginia and the kind of management in vogue includes Drs. Wyndham B. Blanton, Richmond, chairman; Walter B. Martin, Norfolk; Henry B. Mulholland, Charlottesville; Philip S. Smith, Abingdon, and Harry Walker, Richmond. Pursuant to a request from the surgeon general of the U. S. Public Health Service, a committee to deal with the problem of syphilis control has been appointed, consisting of Drs. Ennion S. Williams, Richmond, chairman; Raymond DeV. Kimbrough, Norfolk; Edwin E. Barksdale, Danville, and Dudley C. Smith, Charlottesville.

## WEST VIRGINIA

**Conference of Secretaries.**—The annual conference of secretaries of county medical societies was held at the headquarters of the West Virginia Medical Association in Charleston, January 12. Among those who were to lead discussions were Drs. William S. Fulton, Wheeling, president of the state association; Benjamin H. Swint, Charleston, chairman of the association's advisory committee on social security; Berlin B. Nicholson, secretary of the Academy of Medicine of Parkersburg, and Thomas H. Blake, Charleston, of the state health department.

**Society News.**—Dr. Louis G. Herrmann, Cincinnati, addressed the Cabell County Medical Society in Huntington, December 10, on "Peripheral Vascular Diseases." —Dr.

Charles H. Gay, Martinsburg, and Mr. Joe W. Savage, executive secretary of the West Virginia Medical Association, addressed the Eastern Panhandle Medical Society in Martinsburg, on "Diseases of the Kidney in Infants and Children" and economic problems peculiar to West Virginia. —Dr. Benjamin P. Potter, Secaucus, N. J., addressed the Kanawha Medical Society, Charleston, December 8, on "Tuberculosis from a General Practitioner's Point of View." —Dr. Willis C. Campbell, Memphis, Tenn., addressed the Ohio County Medical Society, Wheeling, January 7, on "Physiologic Principles Applied to the Treatment of Fractures." —At a meeting of the Raleigh County Medical Society, Beckley, December 17, Dr. Archer A. Wilson, Charleston, spoke on injuries to the head.

## PUERTO RICO

**Personal.**—Lucy G. Taliaferro, Sc.D., and William H. Taliaferro, Ph.D., Chicago, will be at the School of Tropical Medicine of the University of Puerto Rico, for the coming three months conducting research on the mechanism of immunity to trichiniasis, a joint project of the University of Chicago and the School of Tropical Medicine. Dr. William H. Taliaferro is dean of the Division of Biological Sciences at Chicago. —Dr. Honorio F. Carrasquillo, Utuado, has been appointed a member of the board of medical examiners.

## GENERAL

**Annual Social Hygiene Meeting.**—The annual meeting of the American Social Hygiene Association will be held at the Hotel Pennsylvania, New York, February 3. The subject of discussion will be "Controversial and Unsettled Questions of Procedure and Public Policy Relating to Programs for the Control of Syphilis and Gonorrhea," and the speakers announced are Drs. Charles Walter Clarke, New York; John F. Mahoney of the U. S. Public Health Service; Henry P. Talbot, Hartford, Conn., and Charles V. Craster, Newark, N. J., and Mr. Alan Johnstone, formerly regional director for law enforcement and protective measures, Army and Navy Training Camp Commissions. Dr. Ray Lyman Wilbur, Stanford University, Calif., and Dr. Thomas Parran, surgeon general, U. S. Public Health Service, will make the introductory addresses and Dr. William F. Snow, general director of the association, will preside.

**Society News.**—Officers of the section on medical sciences (N) of the American Association for the Advancement of Science, elected at the recent meeting in Atlantic City, are Dr. Esmond R. Long, Philadelphia, chairman and a vice president of the association, and Malcolm H. Soule, LL.D., Ann Arbor, Mich., secretary. Forest R. Moulton, Ph.D., formerly professor of astronomy at the University of Chicago, was elected permanent secretary of the association to succeed Henry B. Ward, LL.D., emeritus professor of zoology at the University of Illinois, Urbana. —The American Orthopedic Association will hold its annual meeting in Lincoln and Omaha, Neb., June 2-4. —The annual meeting of the American Heart Association will be held February 1 at its headquarters at 50 West Fiftieth Street, New York. —The American College of Physicians will hold its annual meeting in St. Louis, April 19-23.

**Influenza and Pneumonia.**—Eighty-six major cities of the United States reported to the U. S. Department of Commerce 11,401 deaths during the week ended January 9. This figure is a decided increase over the average number for the corresponding week of the past three years, 9,628, and over the numbers reported for the five preceding weeks, as shown in the following table:

January 9 .....	11,401	December 19.....	9,247
January 2 .....	10,419	December 12.....	8,790
December 26.....	8,548	December 5.....	8,743

The Department of Commerce attributes the excessive mortality to the prevailing epidemic of influenza and pneumonia. The report points out that certain considerations must not be overlooked in the interpretation of these reports. Weekly figures fluctuate widely; some cities are hospital centers for large areas outside the city limits, and the sex, age and racial composition of the cities is not always comparable.

**Certificates for Veteran Public Health Members.**—Eight members who have been affiliated with the American Public Health Association forty years or more were presented with certificates at the recent annual meeting of the association in New Orleans. Dr. John Harvey Kellogg, head of the Battle Creek Sanitarium, Battle Creek, Mich., and Daniel W. Mead, Madison, Wis., received their certificates in person, but the others were unable to attend. Dr. Mazyck P. Ravenel, Columbia, Mo., received the certificate for Dr. William C. Woodward, Chicago, Director, Bureau of Legal Medicine and

## LIVER DEATH A HEPATORENAL SYNDROME

The close association of the liver and the kidneys in the performance of certain metabolic processes dealing with detoxification of various substances by the former and their excretion by the latter suggests a definite interdependence. Disease states of the liver may cause pathologic alterations in the kidneys. Bartlett<sup>1</sup> has described renal complications in infectious diseases of the bile passages. Clairmont, von Haberer, Staeheli, Kehr and others have described cases in which anuria followed cholecystectomy or an operation for the relief of obstructive jaundice. They believe that the anuria is caused by a reflex spasm of the renal vessels and that the origin of the reflex is the damaged liver. This is supported by the histologic determination of contracted capillaries of the glomeruli and of the afferent renal vessels.

Among the hepatic diseases that lead to secondary renal involvement, so-called liver death has come to occupy a prominent position. This refers to death taking place after an operation on the bile tracts or following a traumatic injury to the liver. Heyd<sup>2</sup> was the first to advance the concept of liver death as a postoperative complication. He divided this unusual but distinct postoperative complication into three clinical groups. Patients in group 1 present, as a rule, a history of long-standing disease of the biliary tract but are otherwise apparently good surgical risks. The blood and the urine are normal and there are no signs of organic disease. Following a cholecystectomy, the patient passes into a semicomatose state with rapidly mounting elevation of temperature, and death supervenes in from twenty-four to forty-eight hours. Group 2 is represented by a patient who is jaundiced and who is not as good a risk as the patient in group 1. He is properly prepared for the operation and is not necessarily a bad risk. He makes, as a matter of fact, a satisfactory recovery from one of the routine operations on the gallbladder or the bile tract. After two or three normal days, however, the aspect of the patient changes, with somnolence, irritability, nervousness, rise of temperature, oliguria, coma and death in the next twenty-four or forty-eight hours. In group 3 the patient presents symptoms of calculous cholangitis, perhaps with some involvement of the pancreas. After five or six days of satisfactory progress following an operative procedure, oliguria develops, which may pass on to be total anuria and death with symptoms of uremia. Heyd's observations were soon followed by those of Cave, Stanton, Graham, Helwig, Schutz and Kuhn, Petré, Ravdin and others, so that in 1934 Heuer was able to collect from the literature ninety-five instances of liver death.

A new factor was introduced into the concept of liver death when Furtwaengler in 1927 reported from Clairmont's clinic a case in which a young woman, after an automobile injury, experienced a fatal course precisely like that of the patients in Heyd's group 3. Helwig and Orr reported a case of liver death following traumatic rupture of the liver. Postmortem examination of the two cases revealed, in addition to the traumatic necrosis of the liver tissue, high grade necrosis of the renal cortex. In 1932 Schutz, Helwig and Kuhn<sup>3</sup> reported six cases of liver death. These authors believed that the death was not due to cessation of liver function, since there was no impairment in glycogenesis, nor was there any evidence of failure to deamidize the amino acids, since urea formation was unhampered and a progressive increase in the nitrogenous products in the blood was found in every case. The stools contained bile, and no evidence of any lack of hepatic function was found. The clinical picture of their cases was that of from five to eight normal postoperative days, followed by abdominal distention, vomiting, rise in temperature, oliguria, appearance of albumin, casts and red cells in the urine, increase in the residual blood nitrogen, bleeding into the mucous surfaces, much blood in the vomitus and the stool, coma and death. Postmortem examination revealed pronounced fatty degeneration of the liver, cloudy swelling, leukocytic infiltration, focal hemorrhages and parenchymatous cell necrosis. The most striking histologic observation in the kidneys was degeneration of the epithelium lining the convoluted tubules. Submucous hemorrhages were found with especial frequency in the gastro-intestinal tract and next in the interstitial pulmonary tissue, the skin and the gums. Jaundice was absent, as a rule. Boyce and McFetridge<sup>4</sup> showed that the so-called hepatorenal syndrome may develop in diseases other than those of the liver and the bile tracts; namely, in burns, intestinal obstruction and hyperthyroidism. Weller found in forty-four necropsies on patients dying of hyperthyroidism that the liver was normal in only six.

A number of investigators attempted to reproduce the hepatorenal syndrome in animal experiments. Gundermann in 1913 tied the left portal vein in rabbits and caused atrophy of two thirds of the liver. Oliguria develops, with albumin, casts and red cells in the urine. Boyce and McFetridge were able to reproduce the clinical and pathologic picture of the hepatorenal syndrome in rabbits by first causing an obstruction of the biliary tree and later releasing the obstruction. The most interesting feature of their report was the reproduction of the syndrome by injection into animals of a saline or a watery extract of the liver of a human

#### Social Service and the Weaklings

In the long letter to the *Times*, Lord Dawson has gone to the root of the problem of national health in its politico-medical aspects. He points out that years ago nature's method of selecting the fit was a high birth rate and high infant and adult death rates. Formerly weaklings in body and mind sank to a low economic level, lived precariously and were prone to elimination by diseases such as tuberculosis. Today, through our social services, they receive maintenance and increasing protection from the ravages of disease. The mortality from tuberculosis has been halved in the last twenty-five years. Further, these weaklings often propagate to the disadvantage of the race. This nugatory rendering of nature's rough method of elimination necessitates an alternative policy, which we have not thought out. It should comprise (1) plans to promote fitness during the period of rearing and development, (2) plans to secure that the most fit among youth, from wherever they derive, have every opportunity to get to the forefront, and (3) plans of special and kindly measures for dealing with the inherently unfit. Under the first policy much has already been done. As to the second policy, if the best in body and mind get to the front there will arise a group of leaders of youth who will determine standards and values, to the advantage of the nation economically and racially. From these standards and values the deriving tastes will result a process of unconscious selective mating which will make for fit progeny. Social and educational services ought to be more selective, pushing forward the better and best while at the same time securing for simpler folk training suitable for their simpler spheres of usefulness. At the other end of the scale the fundamentally unfit youth should be given kindly though economical shepherding and elemental training.

Let us beware lest in our desire to be kind to the weaker brethren of today we are not more than unkind to all the brethren of tomorrow. It is relevant to consider the birth rate. During the fifty years 1880-1930 there was a decline in the crude birth rate of 54 per cent in England. The dominant cause is contraception, which is widely and increasingly practiced in all European countries. Its practice is more prominent among the more educated classes, but it has already reached the artisan class and is rapidly penetrating the classes that live by unskilled labor. One potent cause is the fall of the infant death rate from 172 to 57 per thousand births during the last ninety years. Formerly the death rate was the safety valve. But contraception can be misused and in some cases families are too small for the health of the mother. Fit citizens should more than replenish their own places. There is need for motherhood clinics where instruction should be available for all women from the age of 18 onward on sex relations, hygiene and pregnancy and how contraception should be practiced. The burden of our taxation is a deterrent to parenthood. The cost of the social services has increased enormously. This rose from \$515,000,000 in 1925 to \$1,060,000,000 in 1936. In 1941 it will be \$1,500,000,000. Finally, the inherently unfit should be actively discouraged from reproduction. There are some 250,000 mental defectives in this country who are free to marry. Good nurture cannot be a makeweight against bad breeding.

#### Articles by Physicians in the Lay Press

It is held in the profession that physicians should not contribute to the lay press articles which advertise them as practitioners. On the other hand, under certain circumstances it

may be proper that physicians should write for the instruction of the public. Thus to define what may or may not be written is not an easy problem. Advice on the point has been asked of the head office of the British Medical Association, which devotes a section in the *British Medical Journal* to "Problems in Practice," matters of general interest on which individual members seek advice. The official pronouncement is as follows: Topics which have a relation both to medical science and to the health and welfare of the public are discussed from time to time in the lay press. It may be legitimate and even advisable that physicians who can speak with authority on the question at issue should contribute to the discussion. But they ought to make it a condition of publication that laudatory editorial comments or headlines relating to the contributor's professional status or experience shall not be permitted, that his address or photograph shall not be published, and that there shall be no unnecessary display of his medical qualifications and appointments. It is pointed out that there is a special claim that practitioners of established position and authority shall observe these conditions, for their example must necessarily influence the actions of their less well recognized colleagues. Discussions on disputed points of treatment should be avoided. These find their appropriate medium in the professional societies and medical journals.

#### Raw Vegetable Diet in Chronic Rheumatic Conditions

Von Noorden has used a raw vegetable diet in the treatment of chronic rheumatism and has attributed its value chiefly to salt restriction. This treatment has not been adopted in England to any extent. However, in her presidential address to the Section of Therapeutics of the Royal Society of Medicine Dr. Dorothy C. Hare reported a group of twelve cases treated by diet alone, so as to get clear-cut results. They comprised the main types of muscular rheumatism, osteo-arthritis and rheumatoid arthritis. The patients were admitted to the Royal Free Hospital (the London School of Medicine for Women). They were first placed for a week on the ordinary diet. If able, they were up and about for several hours daily and did voluntary exercises in the physical therapy department, where cinematograph records of their movements were made. The diet regimen was in two periods. The first lasted two weeks and in it the food was entirely uncooked. It averaged 2,000 calories daily and consisted of vegetables 14 ounces (salads, tomatoes, roots), citrus fruit 8 ounces (orange, lemon, grapefruit), apple 6 ounces, dried fruit 4 ounces (apricot, prunes, raisins), nuts 2 ounces, crushed oats three-fourths ounce (served after soaking), sugar one lump, salad oil or mayonnaise 2 ounces, 20 per cent cream 3 ounces, milk 12 ounces, no salt, and fluids (tea, water) unrestricted. These gave approximately the food values carbohydrate 145 Gm., protein 35 Gm., fat 143 Gm. After the two weeks the following cooked daily additions were made: vegetable soup, one egg, meat 2 ounces, bread 2 ounces and as uncooked additions butter 1 ounce, cheese 1 ounce and milk 20 ounces. No salt was added to that present in the food. Oil and cream were reduced as necessary. The approximate food values were carbohydrate 146 Gm., protein 66 Gm., fat 142 Gm., calories 2,200. This second diet was given for weeks or months.

Of the twelve patients eight felt definitely better within one to four weeks. Of the other four, two improved up to five or six weeks and then relapsed, and two found no relief at all. The improvement consisted of decrease of pain, stiffness and swelling (symptoms that arise in the soft tissues). Pain arising in joints with active disease of bone and toxic symptoms were not relieved. The cases of muscular rheumatism uncomplicated by definite arthritis gave the best response. Some improvement was seen on the fourth day, and after a fortnight the changes were sometimes striking. The effect was progres-

three excellent photomicrographs illustrating such networks as Auerbach's plexus myentericus, Meissner's plexus subserosus, and the intramural nerve network in the dog's uterine wall and the urinary bladder. The monograph by Schabadasch is unquestionably an important scientific contribution and a credit to the scientists of the Soviet Union.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### CALIFORNIA

**Bill Introduced.**—A. 51 authorizes the board of supervisors of a county maintaining a county hospital to admit pay patients to the county hospital and to charge such patients for the entire value of the services rendered to them, as ascertained pursuant to rules and regulations promulgated by the board. Payment is to be adjusted to the patient's ability to pay. Such patients are to receive medical, surgical or other treatment from qualified physicians of their own choice.

**Society News.**—Dr. Clarence M. Hyland, Los Angeles, addressed the San Diego County Medical Society, January 12, on "Use of Convalescent Serum in Contagious Diseases."—Dr. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, addressed the Los Angeles County Medical Association, January 21, on medical economics. Several changes in the society's bulletin, effective with the January 7 issue, include an increase in size and an improved cover page.—The Alameda County Medical Association was addressed, January 18, by Drs. Harry J. Templeton on "The Evolution of Cutaneous Epitheliomas"; Olin H. Garrison, "Use of Protamine Insulin," and Albert H. Rowe, "Clinical and Experimental Allergy." All are from Oakland.

### GEORGIA

**Health Departments Merge.**—The health department of Americus and the Sumter County Health Department merged, January 1. Dr. William Franklin Castellow, Montgomery, Ala., is the new health officer. He succeeds Dr. Abram J. Davis, resigned. Dr. Davis held the titles of city and county health officer.

### ILLINOIS

**Outbreak of Smallpox.**—Fifteen cases of smallpox were reported in an outbreak at Beardstown and five at Meredosia, according to the state department of health, January 16. The first case at Beardstown was thought to be chickenpox and this error in diagnosis is believed responsible for the spread of the outbreak. All unvaccinated children have been prohibited from attending schools in Beardstown, and similar recommendations have been made to Meredosia. Vigorous vaccination campaigns are being urged by the department.

### Chicago

**Medical School Shares in Rockefeller Gift.**—The General Education Board of the Rockefeller Foundation has given to the University of Chicago \$3,000,000 for the development of the medical school and the improvement of the university generally. Of \$360,000 to be devoted to medicine, \$250,000 continues present grants. The remainder will finance thirty-six beds in Billings Hospital which have already been converted to free beds and ten additional free beds added in the Bobs Roberts Hospital for children through immediate use of the funds. With the increase in beds, 218 of the 519 beds in the various hospitals in the University Clinics will be entirely free. This figure of 218 beds does not include part pay beds or those used as free beds because of special circumstances, although designated as being for paying patients. According to the university, 47.69 per cent of the work done in the clinics in November was free, and this percentage represents the usual average of unpaid service provided. The establishment of the University of Chicago Clinics and medical laboratories, which were formally opened in 1927, was made possible largely through the assistance of the General Education Board.

**Society News.**—The German Medical Society of Chicago was addressed December 8 by Drs. William C. Beck on "The Recognition and Management of Peripheral Arterial Disease" and Samuel Perlstein, "The Electrocardiogram as an Aid in Clinical Medicine."—The Chicago Gynecological Society was addressed, January 15, by Drs. Henry Close Hesselstine on "Experimental and Clinical Therapy of Vulvovaginal Mycosis"; Herbert E. Schmitz, "Mortality and Complications of 3,129 Supracervical Hysteromyomectomies," and Edwin J. DeCosta and Ralph A. Reis, "The Oral Administration of Paraldehyde for Relief of Pain During Labor."—The Chicago Medical Society was addressed, January 20, by Drs. Clarence A. Earle on "Scarlet Fever Prevention"; Louis Rudolph, "Constriction Ring Dystocia," and Edward H. Ochsner, "Treatment of Simple Sprains."—Dr. Theodore Cornbleet, among others, addressed the Chicago Pathological Society, January 11, on "The Role of Calcium in Scleroderma."—The Chicago Council of Medical Women held a joint meeting with the Medical Women's Club, January 13; the speakers included William S. Peterson, Ph.D., on "The Patient and the Weather"; Marian Hood, "Amebiasis with Demonstration of Living Parasites," and Dr. Marie L. Connelly, "Changes Occurring in Hodgkin's Disease."

### INDIANA

**Bill Introduced.**—H. 2, to amend the workmen's compensation act, proposes to extend to sixty days from thirty days the period following an industrial accident during which an employer must pay for medical, hospital and nursing care rendered an injured workman. The bill also proposes to authorize the industrial board to require an employer to furnish such treatment for an additional period not exceeding sixty days, if by reason of the nature of the injury or the process of recovery treatment is necessary for such period.

### MASSACHUSETTS

**New Medical Editor.**—Dr. Robert N. Nye, Boston, has been appointed editor of the *New England Journal of Medicine* to succeed Dr. Walter P. Bowers, who has been managing editor since April 1921. Dr. Nye is 44 years of age and a graduate of Harvard University Medical School, class of 1918. For several years he has been assistant pathologist in charge of bacteriology in the pathologic laboratory of the Boston City Hospital.

**University News.**—Frederick C. Waite, Ph.D., professor of histology and embryology, Western Reserve University School of Medicine, Cleveland, addressed the George A. Bates Society, composed of faculty and students of Tufts College, January 8, on "The Background of Dentistry." He also addressed the Association for the Promotion of University Education in Dentistry in Boston, January 9-10, on "Development of Dentistry in the United States in the Nineteenth Century."

**Students' Health at Harvard.**—A total of 1,463 students, or 20 per cent of the student body, were admitted to Stillman Infirmary of Harvard University, Boston, during the year 1935-1936, according to the first annual report of the recently reorganized department of hygiene. This number spent an average of 3.9 days in the infirmary, while 211 men who were admitted to hospitals spent an average of 12.6 days. There were 28,843 visits made to the various branches of the department of hygiene, but medical excuses from classes were given to only 2,709, representing, it was stated, a considerable reduction from the numbers in former years. The majority of infirmary patients were treated for "acute respiratory infections" under the designation of colds, while sixty-six hospital patients, or 41 per cent, had operations for appendicitis. An additional 15 per cent of the students were sent home to bed. Skiing was responsible for more serious accidents than any other sport, there being recorded a fracture of the femur, two fractures of both bones of the lower leg and one fracture of two vertebrae. Two fractures of the lower leg incurred in hockey and baseball were the only other two serious athletic accidents. Football was responsible for one serious injury, a fractured clavicle.

### MICHIGAN

**Personal.**—Drs. John W. Hawkey, Santa Ana, Calif., and Alois Thuner, Point Loma, Calif., have been elected members emeritus of the Michigan State Medical Society.

**Physician Honored.**—Dr. Archibald D. MacLaren, Port Huron, was guest of honor at a dinner given by the St. Clair County Medical Society January 5. Dr. Howard O. Brush, president of the society, was toastmaster, and Dr. Henry Cook, Flint, president-elect of the state medical society, was among

It is therefore recommended that no probationer under the age of 18 should be employed in wards occupied by phthisical patients. But it is pointed out that the age limit is probably of less importance than the care given to the conditions under which young nurses work. In reply to a questionnaire it was ascertained that the hours of nurses in institutions vary from forty-eight to seventy-seven a week, the average for probationers being about sixty. This is somewhat longer than the period recommended by the College of Nursing.

## PARIS

(From Our Regular Correspondent)

Dec. 22, 1936.

### Meeting of French Orthopedic Society

The eighteenth annual meeting of the French Orthopedic Society took place October 9 at Paris. Professor Etienne Sorrel presided in place of Professor Le Fort of Lille, who was unable to attend. The two subjects discussed this year were spondylolisthesis and the treatment of faulty union following fractures of the ankle. The reporter of the first of these was Dr. Maurice Guillemet of Lyons, who said that spondylolisthesis was until recently regarded as an anatomic curiosity but that it is now in the domain of orthopedic surgery. The condition can be defined as a sliding of one vertebra on that directly below, involving most frequently the fifth lumbar on the sacrum. If the last lumbar vertebra simply projects over the edge of the sacrum the condition is termed spondylosis, whereas if the last lumbar vertebra forms an angle with or falls in front of the sacrum, as rarely occurs, the term spondyloptosis is used. The results of this change in the normal relation of the last lumbar vertebra and the sacrum are modifications in the form and position of the spine, sacrum and pelvis. The entire lumbar spine is displaced posteriorly in a position of lordosis, forming an angle and not a curve. A scoliosis and change in axis of the sacrum may be found as an associated sequela. Spondylolisthesis is not only found in women, as formerly taught, but according to some authors occurs as frequently in men. It has been observed as early as the age of 15 years and even less, and as late as the age of 50. At times it follows an injury such as a fall from a height on the buttocks or knees. In other cases the only apparent cause is fatigue in certain occupations. In general, the congenital etiology is more common than the traumatic. The pain syndrome is the principal clinical feature. The pains vary in intensity, with indefinite localization in the lumbosacral or anal regions and the thighs. Rarely they are referred to the abdomen, leading to erroneous diagnoses of intra-abdominal disorders. In still other cases the clinical picture is that of a femoral or sciatic neuritis. The pains are worse in the upright position and are not relieved by sitting down or even by lying down. The attitude of the patient is characteristic; the trunk seems to be falling forward as though the thorax were trying to enter the pelvis, resulting in a shortening of the entire body length.

There is a sacrolumbar hollow which is not a lordosis but an angle. Latent or masked forms are at times observed in which the lumbar deformity is absent, the pain being the only symptom that attracts attention, and the lumbosacral vertebral displacement is confirmed by the x-ray examination. On the other hand, one sees occasionally cases in which there is no pain or functional disturbances but with outspoken deformity of the spine. In the majority of cases the diagnosis is based on the x-ray appearance, permitting one to exclude a simple painful lordosis, a sacralization of the last lumbar vertebra or a twisted sacrum.

The profile view is the most important, followed by three-quarter and anteroposterior views, the last named to discover associated lesions. The treatment is either orthopedic or operative. The former includes rest in bed with the knees flexed

and trunk raised, radiotherapy, diathermy, and the wearing of a corset for five or six months, at first of plaster and then of leather, molded to the form of the trunk. As surgical measures, bone grafts so as to form a lumbosacral osteosynthesis deserve special mention. The chief indications for operative intervention are inability of the patient to work, intolerable pain and failure of orthopedic treatment.

The discussion was opened by Froehlich of Nancy, who has operated on three of seven women patients by the Albee sacrolumbar graft method. In one of the three the result was very good and in one it was satisfactory, but the third case was a failure. Of four cases treated by orthopedic apparatus, the end result was good in three but poor in the fourth. Graftin of Paris reported five cases (two of spondylosis and three of spondylolisthesis) by the Huc method with satisfactory results. He insisted on roentgenography in the upright position, which revealed a marked displacement in one case, not evident in a film made with the patient lying down. Roederer of Paris divided proposed operations into three groups: (1) those which aim to unite the posterior fixed to the anterior mobile segment, (2) those which fix the anterior segment to the adjacent bones, and (3) those which involve only the posterior segment, solidifying the posterior arcs and the sacrum. Operations in the first of these cannot be carried out because of anatomic and physiologic considerations. Those in the second group have been realized by fixation of the body of the vertebra by the anterior approach. In the third group can be placed the Albee and the Hibbs methods, which have been more successful than any others. Huc of Paris believes that errors have been frequently made in the diagnosis of tilting of the sacrum. Interpretation of films is easy in younger persons but increasingly difficult after the age of 40.

### TREATMENT OF FAULTY UNION FOLLOWING FRACTURES INVOLVING THE ANKLE

The report on the second subject had been prepared by Dr. Paul Padovani of Paris. He divided the displacements of the foot into (a) outward, (b) backward, (c) inward (rare) and (d) forward. The functional disturbances are of as great importance as the deformity. The films of the injured ankle must always be compared with those of the uninjured side. Faulty union is the result either of incomplete reduction of the primary displacement or the recurrence of the latter in the cast or other apparatus or too early use of the limb. Following reduction under fluoroscopic control, the patient should not be allowed to use the limb for at least seven weeks. In some cases a primary open operation is the only means available for reduction of displaced fragments. Secondary operations include osteotomy directly at the seat of fracture or supramalleolar-tibiofibular orthopedic resection and astragalectomy. The last named has been somewhat unjustly discarded because of the difficult technic. The chief reasons for the present unpopularity of astragalectomy are the persistence of pain and the necessity of an additional osteotomy, especially of the outer malleolus. Tibiotarsal resection and arthrodesis have been employed by Kimberley, who reports some good results. The indications for this operation are the same as for astragalectomy. The best type of operation for malunion following fractures of the ankle is osteotomy. Astragalectomy should be done only in old fractures with marked osteophyte formation and changes in the joint cartilages. Arthrodesis or tibiotarsal resection will be reserved for very severe joint deformity and for cases in which an anterior astragalectomy has been followed by persistence of pain.

In the discussion, Boppe of Paris emphasized the difficulty of reduction after osteotomy of the malleoli. He employs the Kirschner method. He has followed up a number of osteotomized patients and found that a painful form of arthritis still existed several years after operation. Maassart of Paris

**Position Open for Director of Social Hygiene Bureau.**—The Municipal Civil Service Commission of New York announces an examination to be held for the position of director of the bureau of social hygiene in the New York City Department of Health. The preliminary requirements are graduation from an accredited medical school, five years' administrative work of which two must have been in venereal disease control, and a license to practice in New York before certification for the appointment. The appointee will carry out the department's program for control of syphilis and gonococcal infection, maintain working relations with hospitals and social agencies, direct record keeping, develop plans for control of venereal disease and direct popular health work in prevention. Applications will be received until February 15 at Room 1400, Municipal Building, Manhattan.

#### NORTH DAKOTA

**Society News.**—At a meeting of the sixth district of the North Dakota State Medical Association in Bismarck, December 1, a symposium on respiratory diseases was presented by Drs. Willis B. Shepard, Linton, Florian E. Schmidt, Chicago, and Charles W. Schoregge, Bismarck. Dr. George M. Constans, Bismarck, was elected president of the district society.

#### OHIO

**University News.**—Dr. Louis N. Katz, Chicago, gave a lecture at an open meeting of the Western Reserve University chapter of Sigma Xi, November 24, on "The Genesis of the Electrocardiogram."

**Dr. Corlett Endows Room for Dermatologists.**—Dr. William T. Corlett, professor emeritus of dermatology, Western Reserve University School of Medicine, Cleveland, has furnished and endowed a room in the Cleveland Medical Library dedicated to research in dermatology and syphilology. Dr. Corlett has given his library, which is said to contain many rare items in several languages, and has placed in the room the mahogany furniture used in his office before his retirement. There are also portraits and busts of famous figures in the history of dermatology. Dr. Corlett, now 82 years old, retired from the faculty of Western Reserve in 1924.

**Public Health Lectures in Cincinnati.**—Dr. William W. Bauer, director of the Bureau of Health and Public Instruction, American Medical Association, Chicago, will give the first lecture in the annual series for the public sponsored by the Academy of Medicine of Cincinnati and the University of Cincinnati College of Medicine. Dr. Bauer will speak January 24 on "What You Should Know About Your Health." Later lectures will be presented by Drs. Dennis E. Jackson, professor of pharmacology and Edward Wendland, professor of materia medica and therapeutics at the university, on "Drugs—Good and Bad"; Robert A. Kehoe, associate professor of physiology, "Industrial Poisons," and Marion A. Blankenhorn, professor of medicine, "The Importance of an Adequate Diet."

#### PENNSYLVANIA

**Bill Passed.**—S. 15, to amend the state constitution so as to prohibit the legislature from making appropriations for charitable, educational or benevolent purposes to any person or community or to any denominational or sectarian institution, has passed the Senate. Such an amendment would affect many private hospitals.

**Personal.**—Dr. James Evans Scheehle, Llanerch, has been appointed coroner of Delaware County. Dr. Scheehle resigned several months ago as state secretary of welfare after serving since January 1935.—Dr. George W. Kehl, chief in surgery on the staff of Reading Hospital for ten years, was honored at a testimonial dinner recently given by his co-workers at the hospital on his retirement. Dr. Pascal Brooke Bland, Philadelphia, was the principal speaker. Dr. Kehl was graduated from the University of Pennsylvania Department of Medicine in 1893 and has been associated with the hospital since 1913. He has been made consulting surgeon.

**Graduate Assembly at Danville.**—A graduate assembly was presented at Geisinger Memorial Hospital, Danville, December 11, under the auspices of the Montour County Medical Society. An operative clinic opened the program, followed by papers given by staff members and by the following guest speakers:

Dr. William O'N. Sherman, Pittsburgh, Treatment of Acute Traumatism.

Dr. Charles Bagley Jr., Baltimore, Injuries to the Head and Brain.

Dr. William J. Merle Scott, Rochester, N. Y., Practical Surgical Applications of Our Knowledge Concerning the Sympathetic Nervous System.

Dr. Sumner L. S. Koch, Chicago, Infections of the Hand.

**Bills Introduced.**—S. 7, to supplement the workmen's compensation act, proposes to make disabilities resulting from a number of stated occupational diseases compensable, among which are poisoning by lead, mercury, phosphorus, arsenic, methanol, carbon bisulfide, naphtha, volatile halogenate hydrocarbons, manganese dioxide, brass, zinc, benzol (benzene) and nitro- and amido-derivatives of benzol; compressed air illness; destruction of tissue by radium or x-rays; chrome ulceration; epitheliomatous cancer or ulceration of the skin or of the corneal surface of the eye resulting from the handling or use of tar pitch, bitumen, mineral oil or paraffin; infection or inflammation of the skin resulting from the handling or contact with oils, cutting compounds, lubricants, dusts, liquid fumes, gases or vapors; anthrax; silicosis, and chronic incapacitating miners' asthma. H. 26 proposes an amendment to the state constitution which would authorize the legislature to classify charitable, educational, benevolent, denominational or sectarian institutions and to appropriate money to such of them as render aid to indigent, diseased, infirm or disabled persons. H. 40, to amend the workmen's compensation act, proposes (1) to extend to one year, from thirty days, the period following an industrial accident during which an employer must pay for medical and hospital care rendered his injured worker, (2) to eliminate the provision in the present law which limits the employer's liability for such services to \$100 and (3) to authorize the injured worker to select his own physician to treat him at the employer's expense.

#### Philadelphia

**University News.**—Temple University will confer the honorary degree of doctor of science on Dr. José Arce, dean of the faculty of medicine, University of Buenos Aires, Argentina, at its Founders' Day exercises February 15.

**Personal.**—Dr. Alexander E. Burke has been appointed a member of the State Board of Medical Education and Licensure to succeed Dr. Arthur C. Morgan, whose term expired.—Dr. Frederick S. Baldi was elected president of the Medical Club of Philadelphia at its annual meeting January 15, at the Bellevue-Stratford.

**Scholarships at College of Pharmacy.**—The alumni association of the Philadelphia College of Pharmacy and Science sponsors seven scholarships annually to defray expenses of the freshman year in courses at the college leading to the baccalaureate degree in biology, chemistry, pharmacy and bacteriology. An entrance examination will be held at the college February 13 in mathematics, science and English and will include an aptitude test. Application blanks may be obtained from the registrar of the college.

#### Pittsburgh

**Society News.**—Dr. Ralph R. Mellon addressed the Allegheny County Medical Society, January 19, on "Recent Chemotherapeutic and Serological Advances in the Treatment of Hemolytic Streptococcal Infections."—Dr. Abraham Levinson, Chicago, addressed the annual scientific meeting of the Pittsburgh Medical Forum, January 16, on "Cerebrospinal Fluid."

#### SOUTH CAROLINA

**Society News.**—Dr. William B. Lyles, Spartanburg, was elected president of the South Carolina Urological Association at the annual meeting December 8. The guest speakers were Drs. Leon Herman, Philadelphia, and William Baird Stuart, Carlisle, Pa.—Dr. William Weston Sr., Columbia, was elected president of the South Carolina Pediatric Society at its annual meeting in Columbia, December 1. The guest speaker was Dr. Charles Armstrong of the U. S. Public Health Service, Washington, D. C., on prevention of anterior poliomyelitis.

**State Health Officer for Twenty-Five Years.**—Members of the staff of the state department of health presented to Dr. James A. Hayne, Columbia, state health officer, a gold watch at Christmas in recognition of his completion of twenty-five years in that position. Dr. Hayne was graduated from the Medical College of the State of South Carolina, Charleston, in 1895 and practiced for several years before becoming health officer. He has been president of the South Carolina Medical Association and of the Conference of State and Provincial Health Authorities of North America and chairman of the Section on Preventive and Industrial Medicine and Public Health of the American Medical Association and of the public health section of the Southern Medical Association. Three sons of Dr. Hayne have become physicians: Drs. James A. Hayne Jr., Isaac Hayne, Congaree, and Theodore B. Hayne, who died of yellow fever while engaged in research in Africa.

stimulation of the normal tissue cells by which the purification of the focus of disease and the process of scarification are substantially aided.

According to Memmesheimer of Essen, the defense mechanism of the skin is set in action in two places, in the epithelium and in the cutis. In the epithelium vitamin D and histamine-like hormones are found. These substances pass through and exert an influence on the entire organism. In the cutis the histiocytes of the tissues, the vascular endothelium and the blood itself all achieve a special capability of defense under the influence of light.

Lomholt of Copenhagen discussed the use of light in the treatment of nontuberculous diseases of the skin. In lupus erythematosus cases that present chronic keratotic plaques of long standing an excellent symptomatic effect is often obtained by irradiation with fractionated doses (applied for from five to thirty minutes).

Cure or amelioration is also many times effected by use of the Finsen-Lomholt lamp in persisting severely itching neurodermatitis localis and in hyperkeratotic chronic eczema. In naevus flammeus the lamp produces a thoroughgoing blanching. It is also used in the treatment of rhinophyma.

Radnai of Budapest called attention to his experimental use of ultraviolet irradiation in syphilis. He has been able to demonstrate that this type of irradiation or a combination with autohemotherapy serves to increase both the reactive capability and the formation of the antisyphilitic immune bodies and the antibodies in the skin. He found that after from thirty to fifty ultraviolet irradiations or after thirty ultraviolet irradiations and twenty autohemic treatments the Wassermann reaction was negative in 60 per cent of the cases. The proper clinical sphere of indication for this combined treatment is late syphilis, especially in the lancinating pains, myalgias, arthralgias and neuralgias that accompany the crises of fully developed tabes. Favorable influence was noted in 142 such cases. For paralyses that show themselves refractive to malariotherapy, Radnai advocates photochemical treatment.

Other papers dealt with the use of radiotherapy in the various forms of tuberculosis. The topic "Light and Public Health" also was discussed but only in its more general aspects.

#### Marriage and Divorce Statistics

As previously mentioned, there were around 650,000 marriages during 1935. From August 1933 to July 1, 1936, marriage subsidy loans were advanced to 602,149 couples (*THE JOURNAL*, Sept. 2, 1933, p. 791). The law stipulates that for each child born in wedlock the amount of indebtedness to the government shall be reduced by 25 per cent. Before the end of June 1936 so many children had been born to the couples in question that 390,445 such reductions had to be made.

Divorce statistics of the past few years are noteworthy. In 1933, 42,000 marriages were dissolved (figures for earlier years may be found in *THE JOURNAL*, May 26, 1934, p. 1774). The divorced couples represented by the foregoing figure were the parents of 36,500 minor children. If to this number is added the number of minor children of couples divorced prior to 1933, an estimated grand total of 300,000 such "divorce orphans" is arrived at. In 1934 a record number of divorces (54,402) was reached; this represented an increase of 28 per cent over 1933 and of 12 per cent over the previous high (in 1921). In 1935 the number of divorces decreased by about 8.5 per cent, 47,784 marriages being dissolved. Per 10,000 existing marriages in 1935 there were only about thirty-three divorces, compared to a corresponding figure of thirty-seven divorces in 1934. It is significant that the decline in the number of divorces in 1935 was effective for every age group with the exception of those couples who had been married as recently as 1934 and 1935. With regard to culpability for the failure of the marriage, the statistics for 1935 virtually coincided with the 1934 figures:

in about 46 per cent of the cases the husband alone was pronounced guilty, in about 20 per cent the wife alone was held responsible and in the remaining cases blame rested on both spouses. Of the couples divorced in 1935, 22,703 (45.6 per cent of the total) had no children whatever, 15,028 couples had one child, 7,199 couples had two children and 4,853 couples had three or more children.

#### Telephonic Apparatus and Tuberculous Infection

Extensive observations by Prof. Ludwig Lange at the National Health Bureau Laboratory for Experimental Research on Tuberculosis have just been made public. The possibilities of a transmission of infection from droplets coughed into the mouthpieces of telephones are theoretically well known. The question is What becomes of the bacilli? Do they perish? Can they again become detached if lodged on the mouthpiece of a telephone? Is there real danger of infection? Any theory of such transmission must be based on the complete desiccation of the droplets on the one hand and a strong current of air from the mouth of the subsequent user of the instrument on the other. The danger of transmission of infection by telephone apparatus is far less from a theoretical standpoint than the danger of crowds or from such a commonly used article as paper currency.

As early as 1889 the National Health Bureau examined three telephones that were equipped with the typical wooden accouterments of the time. The presence of pathogenic organisms and of tubercle bacilli in particular could not be demonstrated. In the years 1913 and 1914 similar examinations of telephones, including instruments used by openly tuberculous persons in sanatoriums, were again carried on, and in no instance was the presence of tubercle bacilli demonstrable. Again in the autumn of 1934 another series of examinations was initiated, largely in response to an ever increasing popular clamor with regard to the suspected transmission of disease and of tuberculosis in particular by telephonic apparatus. These examinations were of peculiar interest, as similar investigations had been undertaken with negative results in England (in 1912) and also in America.

In the more recent investigation in Germany, thirty-four telephones were examined. This material included telephones that had seen service in private residences, public booths, telephone exchanges and, in addition, instruments that had been used by openly tuberculous patients in sanatoriums. A complete examination of each telephone was made. Cultures in various nutrient mediums were tried as well as repeated inoculations of guinea-pigs with the dusts from the various appliances. Of the thirty-four telephones, twenty were allowed to remain uncleaned prior to the examination and fourteen were cleaned according to the daily routine employed by the Deutsche Reichspost for all its public telephones. No tubercle bacilli could be detected on any of the fourteen disinfected instruments. In only two instances could virulent tubercle bacilli be demonstrated in guinea-pigs inoculated with dusts from the twenty uncleaned telephones, although four of these instruments had been intentionally chosen because of the repeated usage to which they had been subjected by tuberculous patients in sanatoriums. In one of these cases only the bovine type bacillus could be cultured out. This case can scarcely be adduced as *incontestable proof* of the presence of virulent tubercle bacilli on the telephone apparatus. In the second case the dust used in inoculation had been removed from an instrument that had been used repeatedly and frequently by a patient with severe open tuberculosis. Only one of the four guinea-pigs used in the experiment actually became ill and in this case it was possible to culture the human type tubercle bacillus. When the apparatus used by the severely tuberculous patient was cleaned, tubercle bacilli could no longer be detected in dust specimens. This is actually the first time that the presence of virulent tubercle bacilli on a telephonic apparatus has been demonstrated.

Legislation, American Medical Association; Dr. Henry D. Chadwick, Boston, for Mr. Robert Spurr Weston, Boston; Henry F. Vaughan, Dr.P.H., Detroit, for George A. Soper, Ph.D., Great Neck, N. Y.; Dr. Angel de la Garza Brito for Dr. Jesús E. Monjaras, Mexico City; Dr. Clarence L. Scamman, New York, for Dr. Charles V. Chapin, Providence, R. I., and Carl E. Buck, Dr.P.H., New York, for Marion Talbot, Chicago.

**Scholarship Available for Boys' Preparatory School.**—The trustees of St. Mark's School, Southborough, Mass., wish to bring to the attention of the medical profession three scholarships to be awarded for boys to enter school next September. Applications for the scholarships will be received at once and should be made by March 1. The examinations will be for the most part of the objective type, for which no special preparation is necessary or desirable, according to the announcement. The school record of the candidate, personal testimony of teachers and others and, wherever possible, personal interviews with a representative of the school will be important factors in the selection. The successful candidates will be expected to meet the usual entrance requirements, taking the entrance examinations in June as follows: for the first form (seventh grade): English and arithmetic; for the second form (eighth grade), English, arithmetic and algebra; for the third form (ninth grade), English, algebra, Latin and French. Further details may be obtained from the Headmaster, St. Mark's School, Southborough, Mass.

**Survey of Research in Mental Hospitals.**—Dr. Winfred Overholser, formerly commissioner of the Massachusetts State Department of Mental Diseases, Boston, has been appointed director of the division of mental hospital research of the National Committee for Mental Hygiene, New York. Dr. Overholser will direct a national survey, it is reported, to ascertain the extent of research being made in institutions for the care of the mentally ill and to find new research clues worthy of development. An advisory committee will be appointed for the survey. Dr. Overholser, a native of Massachusetts, graduated from Boston University School of Medicine in 1916. Until 1924 he served at the Evans Memorial Hospital, and the Westborough, Gardner and Medfield state hospitals. From 1925 to 1930 he was director of the division for the examination of prisoners and was assistant commissioner from 1930 until 1934, when he became commissioner. He taught psychiatry at Boston University School of Medicine for several years and has been lecturer at the Boston University School of Law since 1929. He served as consultant to the National Crime Commission and as chairman of the committee on delinquents and prisons of the First International Congress of Mental Hygiene. He has been a member of the Committee on Psychiatric Jurisprudence of the American Medical Association since 1929. He is a past president of the Massachusetts Psychiatric Association and, in 1936, was president of the New England Society of Psychiatry.

**Medical Bills in Congress.**—*Changes in Status:* H. Res. 60 has passed the House, providing for the appointment of a Select Committee on Government Organization to which will be referred all bills and resolutions introduced in the House concerning reorganization, coordination, consolidation or abolition of organizations or units in the government. H. J. Res. 81 has passed the House, proposing to create a joint congressional committee on government organization to investigate the organization and activities of the several units of the government with the view to determining whether any such units should be coordinated, consolidated, reorganized or abolished. *Bills Introduced:* S. 59, introduced by Senator Bulkley, Ohio, proposes to establish a Bureau of Veterans' Affairs in the Department of the Treasury with the Commissioner of Veterans' Affairs at the head of it, to abolish the Veterans' Administration and transfer its functions to such bureau, and to revise generally the laws relating to veterans. S. 85, introduced by Senator White, Maine, proposes to grant pensions to male nurses who served under contract between April 21, 1898, and Feb. 2, 1901. S. 115, introduced by Senator Lewis, Illinois, and S. 655, introduced by Senator Sheppard, Texas, propose, respectively, to add the name of Gustaf E. Lambert and the name of Roger P. Ames to those honored by the act recognizing the service rendered by Major Walter Reed in the discovery of the cause and means of transmission of yellow fever. S. 383, introduced by Senator Steiwer, Oregon, proposes that any veteran who is a citizen or resident of a state whose laws require a certificate of disability for tax exemption purposes to be signed by an officer of the Veterans' Administration shall, on application, be entitled to receive without cost an annual physical examination by a duly qualified physician designated or approved by the Administrator of Veterans' Affairs.

S. 702, introduced by Senator Barkley and H. R. 2711, introduced by Representative Vinson, both of Kentucky, propose to create a Division of Water Pollution Control in the United States Public Health Service. H. Res. 7, introduced by Representative Daly, Pennsylvania, proposes to request the Administrator of Veterans' Affairs to submit to the House of Representatives a report respecting the naval hospital at Philadelphia, setting forth the facilities of the hospital, the extent of its use by veterans, the need for additional facilities for veterans at such hospital, and certain other facts. H. J. Res. 87, introduced by Representative Randolph, West Virginia, proposes to erect a memorial to Dr. Samuel Alexander Mudd, "in recognition of his unselfish services to his fellow men while being held a prisoner for a crime which he did not commit." H. R. 96, introduced by Representative Smith, Washington, proposes to provide a uniform rate of pension for unmarried Spanish-American War veterans without dependents while hospitalized, and to extend hospitalization to persons recognized as veterans of the Spanish-American War under laws in effect prior to March 20, 1933. H. R. 249, introduced by Representative Colden, California, proposes to construct a marine hospital at Los Angeles Harbor, Los Angeles. H. R. 1532, introduced by Representative Robson, Kentucky, proposes to reestablish the presumptive service connection for disease or disabilities severed by the act of March 20, 1933. H. R. 1538, introduced by Representative Rankin, Mississippi, proposes to provide that in no event shall any person by reason of wilful misconduct be denied any of the service connected benefits under the laws providing relief for veterans of the World War if such misconduct did not interfere during service with the full performance of military or naval duty. H. R. 1622, introduced by Representative Celler, New York, proposes, among other things, to reestablish service connection for a disease, injury or death of a veteran that was severed by the act of March 20, 1933. H. R. 1949, introduced by Representative Lesinski, Michigan, proposes to adjust and equalize benefits for veterans and widows and dependents of veterans. H. R. 1959, introduced by Representative Rankin, Mississippi, proposes to provide increased pensions for veterans of the World War. H. R. 1967, introduced by Representative Taylor, Tennessee, proposes to reenact all laws granting pensions to veterans that were repealed by the act of March 20, 1933. H. R. 2308, introduced by Representative Cannon, Missouri, proposes to reenact all public laws granting medical and hospital treatment, domiciliary care, compensation and other benefits to veterans of the World War that were repealed by the act of March 20, 1933. H. R. 2528, introduced by Representative Welch, California, proposes to confer the benefits of hospitalization and the privileges of the Soldiers' Homes on persons who served in the quartermaster's corps or under the jurisdiction of the Quartermaster General during the war with Spain, the Philippine insurrection or the China relief expedition. H. R. 2530, introduced by Representative Kennedy, Maryland, proposes to provide hospitalization for certain employees in the Bureau of Navigation and Steamboat Inspection of the Department of Commerce and for licensed local pilots of the United States. H. R. 2720, introduced by Representative Fulmer, South Carolina, proposes to authorize the Reconstruction Finance Corporation to make loans to certain hospitals. H. R. 2879, introduced by Representative McGroarty, California, proposes to erect an addition to the existing Veterans' Administration facility, San Fernando, Calif., such addition to consist of 200 beds for the treatment of tuberculous patients. S. 855, introduced by Senator Capper, Kansas, proposes to aid in alleviating the loss caused by sickness.

---

## Government Services

---

### Physicians Wanted for CCC Duty

The government is in need of a number of physicians to assist in the medical work of the Civilian Conservation Corps camps throughout the eighth corps area, which comprises Texas, Colorado, Oklahoma, Arizona and New Mexico. Applicants for these positions must be graduates of class A medical schools. If accepted, they will be given preference of assignments in any one of these five states. Physicians without dependents will receive for this work \$200 a month and those having dependents will receive \$265 a month. All inquiries in connection with application for a position in the Civilian Conservation Corps work in the eighth corps area should be addressed to the Surgeon, Headquarters Eighth Corps Area, Fort Sam Houston, Texas.

## JAPAN

(From Our Regular Correspondent)

Nov. 15, 1936.

## A Study of Intermarriage

On the coast of western Japan called Oita there is a small fishing village known as Usuki, where the inhabitants have strictly kept the custom of intermarriage for hundreds of years and are said never to have married the people of other villages in the neighborhood. Dr. Takeshi Ikemi, who has been investigating the biologic influence of intermarriage in the village since 1933, reports that, according to tradition, this village was settled in 1605. The villagers still believe that they are the descendants of a noble family which was obliged to flee in the civil war of the sixteenth century. There are 135 families having 1,786 members in all (904 men and 882 women). They have never mingled with other villagers or townsmen except in business transactions; consequently their habits and customs are quite different from other Japanese. The ceremonies of coming of age, marriage, burial, ancestral worship, and bringing up children are all held in their own way within their own village, and they strictly refuse to be assimilated. They are somewhat ferocious and sly, but sometimes are quite candid. The men engage in fishing and a little farming, while the women deal in the fish which the men collect and dry. They have no religious faith in its true sense, and they think little of schooling, partly because they are too poor to send their children to school. Although the children are not regular attendants at school, an investigation of the school records shows that they generally do well at school. Thus intermarriage never affected their intellectual faculties. Crime is rare. During the last ten years seven violated the fishing law, four injured others, four did some stealing, four broke the law of weights and measures, eight were charged with gambling, one cheated others, two were robbers, five interfered with

birth rate, in comparison to that of the two neighboring villages, is given in table 1. This table shows that intermarriage does not affect the birth rate. Stillbirths are uncommon. The death rate is given in table 2.

There are now twenty-seven couples who married cousins. Through various inquiries, the following facts have been obtained: When the parents are both excellent mentally and physically, 80 per cent of the children are as excellent as their parents, 20 per cent are good, and none are worse than the parents. If the parents are good though not excellent, 15 per cent of the children are excellent, 75 per cent are as good as

TABLE 2.—Death Rate \*

Village Name	Population	Deaths				
		1928	1929	1930	1931	1932
Usuki.....	1,786					
Boy.....		22 (1.23)	27 (1.51)	26 (1.40)	23 (1.56)	20 (1.11)
Girl.....		16 (0.80)	20 (1.11)	23 (1.28)	18 (1.0)	24 (1.34)
Next village..	1,383					
Boy.....		13 (0.94)	13 (0.94)	20 (1.45)	20 (1.45)	16 (1.15)
Girl.....		9 (0.65)	16 (1.15)	15 (1.08)	19 (1.37)	9 (0.65)
Next but one	1,072					
Boy.....		9 (0.83)	17 (1.59)	11 (1.02)	9 (0.83)	11 (1.02)
Girl.....		12 (1.11)	14 (1.305)	7 (0.65)	13 (1.21)	7 (0.65)

\* Figures in parentheses indicate percentages.

their parents and 10 per cent are not as good as the parents. On the contrary, if neither of the parents is good, the children are all inferior to the children of other families at large. If the parents are both good physically but not mentally, the children are all good physically, 10 per cent of them are excellent mentally, 70 per cent are mentally good and 20 per cent are inferior. To sum up, when the excellent are married, no bad results are to be found.

## Institutional Celebrations

The golden jubilee of the Military Medical College was celebrated November 7 before the four imperial princes and 1,200 other attendants. This school was established in 1886, and since then 5,165 graduates have been turned over to the military. The Japan Military Medical Association joined in the celebration. As a memorial, the school history was compiled and published. A memorial tower will be erected by next April and the memorial lecture room will be completed by next fall.

Another jubilee was held by the Japan Red Cross Society Hospital in Tokyo, and at the same time the completion of an outpatient building was celebrated. The building cost more than a million yen, has 365 beds, and the equipment of the roentgenotherapy department is said to be the greatest in the Orient. The hospital was established Nov. 17, 1886.

## Marriages

MAURICE ALEXANDER KUGEL, New York, to Miss Annie Laurie Harrison of Liberty, S. C., in Fort Myers, Fla., Oct. 4, 1936.

JOSEPH J. REICHMAN, Mount Pleasant, Pa., to Miss Bessie Irene Comins of Mount Pleasant, Mich., Oct. 1, 1936.

WILLIAM DEWEY HALL, Raleigh, N. C., to Miss Sue Ruth Hutto of Gaston, S. C., in Raleigh, Oct. 17, 1936.

CLYDE G. O'BRIEN, Appomattox, Va., to Miss Ellen Elizabeth Sweizer, of Elm Grove, W. Va., Oct. 11, 1936.

RALPH GIBSON FLEMING, North Side, N. C., to Miss Sue Fleming Thompson of Creedmor, Oct. 15, 1936.

SOUTHGATE LEIGH JR. to Miss Maud Paine Winborne, both of Norfolk, Va., in Richmond, Nov. 3, 1936.

FRANKLIN SMITH CROCKETT, Lafayette, Ind., to Miss Henrietta Coleman of Rushville, January 2.

TABLE 1.—Birth Rate \*

\* Figures in parentheses indicate percentages.

government officials in the execution of their duty, and three other derelictions brought the total instances of malfeasance to thirty-eight. Judging from this, it may be affirmed that intermarriage does not bring about the degeneration of mental control. This number of violations is small when compared with that of the neighboring villages or towns.

The sanitary knowledge of the people is meager; they have epidemic diseases, such as dysentery and cholera, but there is never any serious hereditary disease. Leprosy, syphilis and elephantiasis at present are not seen among them. Neither color blindness nor insanity occurs. The constitution of the people is strong and they are good wrestlers in spite of their taking very simple food. In the physical examination for conscription, these villagers have always ranked first, in that prefecture, with respect to health and constitution. In their daily life the men are quiet and amiable, while the women are talkative. When a quarrel does occur the women are usually the leaders. However, they are usually kind and good to one another, especially to those in distress. Divorce is rare. The

sive up to discharge and afterward. One patient, a saleswoman aged 49, had been unable to work for two years in spite of continuous physical treatments. After six weeks on the diet she resumed work and has continued without interruption for five months. The cinematograph records showed the stiff awkward movements before treatment and almost normal movements three or four weeks later.

Patients with rheumatoid arthritis obtained some relief of pain and stiffness at first, but the toxic symptoms remained apparently uninfluenced for many weeks. The only patient given continuous diet treatment for several months made a remarkable improvement. In a woman of 53 the disease had begun two years previously and was of the severe progressive type. All the joints were involved, the hips and knees most severely, and she had been unable to sit or move for six weeks before admission and cried with pain when moved in bed. X-ray examination showed only slight changes in the bones. There were toxic symptoms with wasting, sweating, occasional low fever and anemia. Under the diet she made slow progress, relief of pain preceding improvement in toxic symptoms. She gradually gained weight, and the fever and anemia improved. After the third month massage was given in addition to the diet. After six months she could shuffle a few steps on sticks and was free from acute pain.

Dr. Hare attributed the rapid effect to the low sodium intake. The sodium content of the vegetable foods being extremely small and no added salt being allowed, there was a rapid loss of tissue fluid. This caused a rapid fall of weight in the first week, though weight was gained on exactly the same diet in the following week. The fluid intake was not limited at any period. She referred to the recent work of R. A. McCance on sodium restriction, which appears to explain her results. The factor of abnormal retention of tissue fluids in chronic rheumatism has been emphasized by Ralph Pemberton. Under-nutrition was not a factor in producing the results. She insisted on the importance of the addition of adequate protein and fat to the vegetable diet and thought the abundant supply of vitamin B and C of undoubted value.

#### A British System of Physical Exercises

Great attention is now being given in this country to the problems of public health and physical efficiency. A team of boys from the Betteshanger School, Eastry, Kent, which has given demonstrations at a number of public schools, gave in London, before members of the Parents' Association, a display of a British system known as "basic physical training" because its movements are designed to provide a basis of physical development necessary to give balance, poise and fitness as a preliminary to the playing of games or further forms of physical culture. At Betteshanger School remedial exercises are first given to the boys who need them. Subsequently the course of training of each boy is divided into three sets of movements. The first consists of breathing exercises to secure full expansion and development of the lungs; the second, to teach correct posture and to remedy defects such as flat feet, weak abdominal muscles, spinal curvature and round shoulders; and the third, to give the fullest possible muscle control. Mr. Evans, the headmaster, explained that after examining physical training systems in the United States and Scandinavia he was induced to try a purely British system and found the results much superior to anything he had seen abroad. That system had been tried at Betteshanger and half a dozen other schools. If adopted on a national scale, it would put British boys and girls in the front rank for physique and fitness. In view of the national movement now taking shape to provide the nation with the best facilities for physical training, he was anxious that every system, including "basic physical training," should be examined before any attempt was made to standardize training in this country.

#### The Nutrition of the People

The question of malnutrition continues to be a matter of political controversy. Sir Kingsley Wood, minister of health, received a deputation on the question from the Standing Joint Committee of Industrial Women's Organizations. He said that malnutrition was a word much used and much abused. The word was not, of course, solely concerned with lack of food, although it was an important factor. Sir John Orr (dietitian) and other experts who advised the ministry were agreed that there was need for further investigation. The Ministry of Health's nutrition advisory committee was actively pursuing its work, and he had just arranged for a number of detailed dietary surveys to ascertain the consumption of various kinds of food by different households. Some investigations of this sort had already been made in industrial areas in the north of England. The milk in schools scheme was probably the largest experiment in child nutrition in the world. It was now in operation in schools containing over 90 per cent of the elementary school population, but rather less than half the children were taking advantage of it. Examination was now proceeding as to the best means of increasing consumption, but it was already clear that poverty was not the prime difficulty. It was needful to get a greater appreciation of the value of milk among both children and parents.

#### The Public Health

The annual report of the chief medical officer of the Ministry of Health for 1935 shows that the population of England and Wales is just over 40 million. The number of births was 598,756, a slight increase on the previous year. The infant mortality was the lowest on record, 57 per thousand births, only half that of thirty years ago. The fall in the birth rate and the increased longevity are producing a gradual aging of the population. At the beginning of the century 520 out of every thousand persons were under the age of 25 years; now the number is only 388. At the former period forty-seven out of a thousand were over 65; now the number is eighty-one. Up to the present the fall in the death rate has compensated for the falling birth rate, but we have now reached a point at which not much further improvement in the death rate can be expected. By the middle of the century the population may attain its maximum and thereafter decline. The most prevalent infectious diseases were scarlet fever (120,456 cases) and diphtheria (65,084 cases).

#### Smallpox Infection from Raw Cotton

This country has been free for a long time from smallpox in the form of variola major, but four cases have occurred at Oldham which can be traced only to the handling of raw cotton at a mill. The first case occurred in a vaccinated married woman who worked in the cardroom. The three other cases occurred in her husband, who was vaccinated in 1916, in her son, aged 15, who had never been vaccinated, and in an unvaccinated woman who had been in contact with the original patient. The diagnosis of smallpox was not established early enough in the first case to ensure the successful vaccination of contacts, of whom there were at least ninety-eight in the woman's place of work and twelve at her home. Cotton as a vehicle of smallpox infection has frequently been suspected in the past. In 1913 cases were reported at Oldham as probably due to such infection.

#### Tuberculous Infection of Nurses

A subcommittee of the Joint Tuberculosis Council has submitted an important report on tuberculous infection of nurses. Particular attention was given to the age of entry to the profession, which is usually 18 years, but shortage of candidates has reduced the age to 17 in some areas. In view of the special susceptibility of adolescent females to pulmonary tuberculosis, it is considered undesirable that young girls should be employed.

Walter Herman Miller ☉ Portland, Ore.; University of Oregon Medical School, Portland, 1922; formerly Clackamas County physician and health officer; aged 39; died, Nov. 15, 1936, of multiple sclerosis.

Henry Clay Lloyd ☉ Hobart, Okla.; Medical College of Ohio, Cincinnati, 1901; past president of the Kiowa County Medical Society; on the staff of the General Hospital; aged 59; died, Nov. 17, 1936.

Daniel E. Keys, Spokane, Wash.; St. Louis College of Physicians and Surgeons, 1893; for many years a druggist; formerly coroner of Mullan, Idaho; aged 66; died, Nov. 19, 1936, of heart disease.

Benjamin Lowen Hume ☉ Mallory, W. Va.; Medical College of Virginia, Richmond, 1900; formerly coroner of Cabell County; aged 62; died, Nov. 26, 1936, in the Mercy Hospital, Logan, of pneumonia.

William Gabriel Kiebler, Enid, Okla.; University of Louisville (Ky.) Medical Department, 1905; member of the Oklahoma State Medical Association; aged 53; died, Nov. 29, 1936, of pneumonia.

Hardman Nathan Kinnear, Oberlin, Ohio; Western Reserve University Medical Department, Cleveland, 1882; for many years a missionary in China; aged 76; died recently in Baton Rouge, La.

Frank Creighton Shute, Opelousas, La.; Tulane University of Louisiana Medical Department, New Orleans, 1904; member of the Louisiana State Medical Society; aged 57; died in November 1936.

William Washington Liles, Gainesville, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899; member of the Medical Association of Georgia; aged 61; died, Nov. 6, 1936.

John A. Voorhees, Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; aged 68; died, Nov. 29, 1936, in Bay Ridge Hospital, of pneumonia.

Francis Edward Park, Washington, D. C.; Howard University College of Medicine, Washington, 1886; aged 82; died, Nov. 12, 1936, in the Garfield Hospital, of injuries received in a fall.

John T. Wray, New Albany, Ind.; University of Louisville (Ky.) Medical Department, 1898; member of the Indiana State Medical Association; aged 65; died, Nov. 6, 1936, of arteriosclerosis.

Percy Albert Sloane, Houston, Texas; Baylor University College of Medicine, Dallas, 1914; member of the State Medical Association of Texas; aged 45; died, Nov. 24, 1936, of angina pectoris.

Albert C. Speers, Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1889; aged 71; died, Nov. 16, 1936, in the Montefiore Hospital, of cerebral hemorrhage.

Everett Carlisle Major, Latta, S. C.; Atlanta (Ga.) College of Physicians and Surgeons, 1905; served during the World War; aged 56; died, Nov. 26, 1936, of coronary occlusion.

Herman Elof Almquist, Los Angeles; Loyola University School of Medicine, Chicago, 1919; formerly a practitioner in Minneapolis; aged 52; died, Nov. 18, 1936, of portal cirrhosis.

Tilman Ramsey, Pineville, Ky.; University of Tennessee Medical Department, Nashville, 1899; member of the Kentucky State Medical Association; aged 61; died, Nov. 19, 1936.

Simon Baer ☉ Galveston, Texas; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1924; aged 37; died, Nov. 17, 1936, of carcinoma of the stomach.

Edward J. Ver Wayne, Evansville, Ind.; Starling Medical College, Columbus, 1897; aged 62; died, Nov. 22, 1936, in St. Mary's Hospital, of chronic nephritis and myocarditis.

John M. Taylor, Mena, Ark.; University Medical College of Kansas City, Mo., 1898; member of the Arkansas Medical Society; aged 68; died, Nov. 15, 1936, of angina pectoris.

Moses Aronson ☉ New York; Universität Zürich Medizinische Fakultät, Switzerland, 1883; on the staff of the Bronx Hospital; aged 82; died, Dec. 3, 1936, of heart disease.

Dexter Alvin Buck, La Porte, Ind.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; served during the World War; aged 65; died, Nov. 9, 1936.

Mary Fussell Voeglein, Baltimore; Woman's Medical College of Baltimore, 1901; aged 69; was found dead in bed, Nov. 9, 1936, of myocarditis and diabetes mellitus.

James Haslett Thompson, Enterprise, Ore.; Western Pennsylvania Medical College, Pittsburgh, 1896; served during the World War; aged 68; died, Nov. 20, 1936.

Ellis L. Gibson, Alicia, Ark. (licensed in Arkansas in 1903); member of the Arkansas Medical Society; aged 64; died, Nov. 23, 1936, of dilatation of the heart.

Alexander Gillespie, Edmonton, Alta., Canada; Trinity Medical College, Toronto, Ont., 1884; L.R.C.P., Edinburgh, Scotland, 1884; aged 82; died, Nov. 12, 1936.

Frank Sandfos, Ballwin, Mo.; St. Louis College of Physicians and Surgeons, 1894; aged 64; died, Nov. 26, 1936, in the Deaconess Hospital, St. Louis, of pneumonia.

Norma Mabel Baldwin Kinney, Austin, Texas; Hahnemann Medical College and Hospital, Chicago, 1905; aged 66; died, Nov. 27, 1936, of cerebral hemorrhage.

Samuel James Morrow, Knoxville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1878; aged 83; died, Nov. 7, 1936, in the Fort Sanders Hospital.

Edward Charles Machle, Tacoma, Wash.; Jefferson Medical College of Philadelphia, 1889; formerly a medical missionary in China; aged 77; died, Nov. 30, 1936.

Frank Calvin Atchison, Norwich, Conn. (licensed in Connecticut in 1893); aged 64; died, Nov. 10, 1936, of hypertrophy of the prostate, pyelonephritis and uremia.

Samuel Percival Terry, Alameda, Calif.; Central College of Physicians and Surgeons, Indianapolis, 1896; aged 75; died, Nov. 6, 1936, of cerebral hemorrhage.

Andrew Harry Clarke, Jackson, Tenn. (licensed in Tennessee in 1889); aged 84; died, Nov. 30, 1936, in the Webb-Williamson Hospital-Clinic, of hiccups.

Jacob Smith Petersen, Oakland, Calif.; Niagara University Medical Department, Buffalo, 1891; aged 84; died, Nov. 18, 1936, of arteriosclerosis.

James Alexander La Rue, Pulaski, Tenn.; College of Physicians and Surgeons, Baltimore, 1876; aged 86; died, Nov. 24, 1936, of cerebral embolism.

George W. Charlton, Antioch, Tenn.; University of Nashville Medical Department, 1875; aged 85; died, Nov. 21, 1936, of pulmonary tuberculosis.

William Irvine Hamer, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1919; aged 42; died suddenly, Nov. 17, 1936.

David Richie Shepler, West Newton, Pa.; Baltimore University School of Medicine, 1903; aged 59; died, Nov. 30, 1936, of coronary thrombosis.

William Thomas Shelburne, Indianapolis; Medical College of Indiana, Indianapolis, 1889; aged 79; died, Nov. 17, 1936, of coronary thrombosis.

Samuel Herbert Neal ☉ Philadelphia; Medico-Chirurgical College of Philadelphia, 1895; aged 65; died suddenly, Nov. 7, 1936, of heart disease.

Clement Howard Hallowell, Billerica, Mass.; Boston University School of Medicine, 1879; aged 82; died, Nov. 13, 1936, of arteriosclerosis.

W. R. Tennison, Ponta, Texas; Missouri Medical College, St. Louis, 1878; aged 83; died, Nov. 12, 1936, in Summerfield, of heart disease.

Ralph W. Van Horn, Findlay, Ohio; Eclectic Medical Institute, Cincinnati, 1889; aged 69; died, Nov. 20, 1936, of arteriosclerosis.

James Luther Shilt, Dayton, Ohio; Eclectic Medical Institute, Cincinnati, 1886; aged 76; died, Nov. 7, 1936, of cerebral hemorrhage.

Thomas T. Bays, Hitchens, Ky.; Kentucky University Medical Department, Louisville, 1903; aged 61; died, Oct. 30, 1936.

Harry Hewitt Hooven, Harford, Pa.; University of Maryland School of Medicine, Baltimore, 1892; aged 67; died, Oct. 30, 1936.

John Willis Archerd, Crookston, Neb.; Omaha Medical College, 1891; aged 79; died, Nov. 5, 1936, of cerebral hemorrhage.

Valentine Buechel Jr., Louisville, Ky.; Kentucky School of Medicine, Louisville, 1894; aged 70; died in November 1936.

Tobias Sigel ☉ Detroit; Detroit College of Medicine, 1859; aged 74; died, Nov. 23, 1936, of cerebral hemorrhage.

William James Milne, Blyth, Ont., Canada; Trinity Medical College, Toronto, 1889; died, Nov. 4, 1936.

prefers astragalectomy in older cases in which one encounters, in addition to joint changes, a retraction of tendons and an abundant amount of scar tissue. Tavernier of Lyons also believed that, when reduction is not possible by other means, astragalectomy is the final resort, in spite of the lack of uniformity of the results and the fact that a certain number of patients continue to have pain in walking.

#### Attending Staffs of Public Hospitals to Be Compensated by Pay Patients

There is a sharp line of demarcation here between public hospitals supported by the local governing bodies and private (pay) institutions (*maisons de santé*). There are comparatively few public institutions in France in which patients who are unable to pay are housed in separate portions of the same buildings from those who can do so. This is especially true of smaller communities; hence the paying and the free patients are treated in the same wards. The injustice of asking the medical staffs of such mixed free and pay institutions to treat the pay patients without any remuneration has been the source of many complaints by the organized profession. A recent decree (Feb. 21, 1936) of the government states that the physicians and surgeons of public hospitals have the right to receive special remuneration for services rendered to pay patients. However, such fees shall be collected by the hospital and then divided among the members of the staff in a manner to be agreed on between the hospital administrator and the staff.

#### One Thousand Personal Observations on Pulmonary Tuberculosis in Children

At the October 13 meeting of the Académie de médecine a paper on the different forms of pulmonary tuberculosis in children based on 1,000 cases was read by Armand-Delille, Lestocquoy, Bayle and Lebreton. The incidence of the disease decreases after the first few years of life (forty-one cases between the ages of 9 and 10 years, as compared to ninety-two between 1 and 2 years). The incidence, however, increases rapidly after the age of 12 years, to reach the high figure of 156 between the ages of 14 and 15 years. During the first four years of life, only primary infection is encountered. After the fifth year a division is more difficult because the splenopneumonias and acute tuberculous pneumonias are not necessarily manifestations, as some pediatricians wrongly maintain, of a primary infection. Before the age of 4 years, three types of gangliopulmonary tuberculosis are to be seen; the first is characterized by extensive fatal caseous pneumonia lesions, the second by widespread pneumonic foci but regressive and associated with adenopathy. The third type is characterized by a rapid fatal military tuberculosis. The primary infection form of tuberculosis in younger children, like the reinfection form of older children, involves the right apex in the majority of cases.

#### Necessity of Routine Radiography in Accident Cases

Two recent medicolegal cases are of interest in showing that it is advisable in every accident case in which there is a suspicion of a fracture or dislocation that the physician or surgeon in charge should refuse to assume all responsibility unless the patient consents to have an x-ray examination made as soon as possible after the accident.

In the first suit for damages, a physician was called to take care of a backward dislocation of the shoulder, which was difficult to diagnose by palpation. As a result of nonreduction there was marked permanent functional disability. The husband of the plaintiff claimed that an x-ray examination should have been made. The defendant maintained that he had asked for the application of this method of diagnosis but that the plaintiff had refused to have this done. The jury decided in favor of the defendant. Dr. J. Noir, who reported the case in the November 22 *Concours médical*, states that whenever an

injured person refuses to have an x-ray examination for a suspected fracture or dislocation such a refusal should be in writing and signed in the presence of two witnesses.

In the second damage suit, a diagnosis of a simple comminuted fracture of the head of the humerus was made by palpation by the attending surgeon. The patient requested that an x-ray examination be made but was told that this would be superfluous. Seventeen days later, during the absence of the attending surgeon, his assistant had an x-ray examination made. This revealed a subcoracoid dislocation of the humerus without an accompanying fracture. Following reduction, a paralysis of the injured right arm was noted. The patient was an artist and hence unable to earn a living because of inability to use the arm. Experts appointed by the court estimated the incapacity to be 75 per cent but were unable to state whether or not the paralysis was the result of the unrecognized dislocation. A verdict of 160,000 francs (about \$8,000) was given in favor of the plaintiff. This verdict was to a great extent due to the refusal of the first attending surgeon to have an x-ray examination made.

#### Medal Presented to Laryngologist

Prof. Fernand Lemaître, ear, nose and throat specialist, was recently named Commander of the Legion of Honor. To commemorate this recognition of his distinguished services and also the twenty-fifth anniversary of his occupancy of the position of ear, nose and throat physician to the public hospitals of Paris, his former pupils and friends presented Professor Lemaître with a special medal December 10 at the Lariboisière Hospital. His clinic at the latter has been visited by many foreign specialists.

#### The French Surgical Congress

At the 1936 session (held at Paris October 9) Inspector General Rouvillois of the French army was elected president and Dr. Leon Imbert of Marseilles vice president for the 1937 meeting. The subjects selected for discussion for next year's congress are (1) physiologic pathology of burns, (2) treatment of fractures of the leg, and (3) surgical treatment of embolism of the extremities.

#### BERLIN

(From Our Regular Correspondent)

Dec. 7, 1936.

#### The Congress for Research on Light

The third international congress for research on light was held at Wiesbaden in September. Professor Moede of Berlin has investigated the problem of eye fatigue and has sought to establish an equivalent for the power of the eye and beyond that for the individual constitution itself, which would insure an amount of work that would not fatigue. Practical examination of the capability of an eye to carry on continued close work in industrial occupations demonstrates the extraordinary powers of resistance possessed by the organ even in the presence of severe defects. Nevertheless optimal working conditions for the eye must be created. If the eye becomes fatigued, there appear manifestations of irritation and of decrease in function; basal functions also are altered, wholly apart from the influence on the organism as a whole.

Professor Birch-Hirschfeld, Koenigsberg ophthalmologist, discussed the favorable therapeutic results from the use of ultraviolet rays in disorders of the eye. Ultraviolet rays have proved their worth in the course of the last eighteen years from their use in a vast amount of clinical material. They have for example reduced the proportion of losses in *ulcus serpens* from 30 per cent to 6 per cent. The rays have likewise been productive of favorable results in other diseases of the cornea, conjunctiva and sclera. The curative effect of ultraviolet rays often depends not on their bactericidal capability but on a

Then the index finger is given a half turn forward. This results in a spiral twist and the formation of a cone. The twisted cone is then cut free from the tape. In twisting the cone there should be ample overlapping so that the cone can be made wider if necessary. The overlapping edge is smoothed down until the joining disappears and a smooth surface results. When the cone is placed in the radical cavity to make the mold, the overlapping edge is placed posteriorly so that it lies in the bowl. The tip of the cone is filled with melted paraffin for about a quarter of an inch. It is easy to scrape enough paraffin for this from the waste ends of gauze. The object of the solid tip is to make an accurate mold of the middle ear and the region of the aditus. If the meshes of the gauze show on the surface of the cone, the cone should be dipped in melted paraffin. The longer the operator intends to leave the mold in place, the more care he should take to have a thick coating; because if the gauze becomes exposed, as it did in one case in which the mold was left in three weeks, the mold changes into a gauze plug, starts up granulations and defeats the purpose of the whole procedure. The cone made, the epinephrine gauze is removed from the radical cavity and the paraffin cone placed in it. The handle of the ordinary searcher is used to tampon the cone into place and to make it fit all parts of the cavity, especial care being taken to get an accurate fit in the middle ear. If the meatal flap has not been cut, this is now done. Dr. H. P. Mosher, after much experimenting, has returned to the old Koerner flap. In one case after this flap was made it was cut off and the result was just as good as in the cases in which the meatal flap was left. The mold made, it is left in place for hemostatic purposes while the graft is being cut. The mold is so easy to make that it is worth while to make a second one, perhaps not so carefully as the first, and to leave this in place while the graft is being cut. It takes a minute at least to arrange the skin graft nicely on the mold and, while this is being done, the radical cavity more or less fills with blood and has to be wiped out again. By using two molds, this can be prevented. Experience has shown that it is important to have the mold trimmed flush with the surface of the mastoid and not project. If it does, it interferes with the obtaining of primary healing. If a meatal flap is used, it is tucked in place back of the mold and the cavity of the mold is filled with ordinary gauze. The mastoid wound is closed for its whole length. If the operator prefers, the lower half of the incision can be left open and a drain inserted. If this is done after the drain and the mold have been removed the unsutured part of the incision falls together and heals promptly. It is well to leave the mold in place from five to ten days. As long as the incision does not become puffy or red, in other words, when primary healing goes on smoothly, it is a sign that the mold is being well tolerated. If much discharge appears at the meatus, this is a sign that the mold should be removed. As was pointed out before, if the mold is left in long enough for the wax to be melted away sufficiently to expose the gauze, the purpose of the mold is defeated.

When it is decided to remove the mold, the gauze that is packed into the cavity of the mold is taken out and then the sides of the mold are collapsed on each other and the mold is taken out. Usually the skin graft is left behind and adherent to the sides of the radical cavity. It is a great satisfaction to see the graft left behind and fitting snugly in place. It is a great contrast to what happens when the gauze plug for carrying the graft is used.

When the mold was first used, Dr. Mosher left the incision open and drained for its full length, closing the incision secondarily. Next he closed the upper half of the incision and drained the lower half. It was found that the lower half of the incision would close of itself. Dr. Frederic L. Bogan proved that, if the edges of the mastoid mold are trimmed flush or a little below the surface of the mastoid cavity, primary union can be secured in most cases. In the early days of experimenting with the mold it was made of solid paraffin and was removed through the postauricular incision. The basket mold can be easily removed through the meatus.

#### PREGNANCY AND PERNICIOUS ANEMIA

To the Editor:—Please advise as to the treatment and prognosis of a patient with a moderate degree of pernicious anemia who is six months pregnant. De Lee says "Pregnancy should be terminated as soon as the diagnosis is made." HARRY F. WATT, M.D., Ocala, Fla.

ANSWER.—True pernicious anemia is rare during pregnancy but a "pseudo pernicious anemia" in its milder forms is observed occasionally. The mildest or hypochronic anemia is rather common. Esch reports six cases of pseudo pernicious anemia which he thought were toxicemic in origin. If there

are heart murmurs, leukocytosis and fever, one should think of endocarditis. After a positive diagnosis of true pernicious anemia has been settled, the treatment is as usual. Increased doses of liver extract should be given intramuscularly, enough to keep the blood count well above normal, and 7 Gm. of iron as ferrous carbonate or ferric ammonium citrate daily added if necessary. One might add vitamins A and C to the diet.

If the blood examinations of this patient show no improvement or a deterioration, the pregnancy should be terminated.

In this case it might be possible to tide the patient along at least to viability of the child and, if improvement is evident, even to term.

#### MALIGNANT HYPERTENSION

To the Editor:—A white man, aged 46, has been suffering from what is said to be "kidney trouble and high blood pressure" for the past six or eight weeks. His past history is negative. His father, aged 69, has been suffering from hypertension for a long time, probably of arteriosclerotic origin. At the time he consulted a physician he noticed that he became tired easily and felt weak in his legs after climbing the subway stairs. Later on he complained of headache and pain in the suboccipital region (having slept well he awoke with severe headache and pain behind the eyes, for which Bromo-Seltzer had been the only remedy). He had had probably all kinds of medicine and a strict diet, mostly vegetarian and salt free. April 3, the urine examination revealed a small amount of albumin, no sugar, no acetone, from 1 to 2 leukocytes per high power field, and 12 hyaline, 3 moderate granulated and 4 epithelial casts. About five days ago I was called, because the patient had become very ill, had vomited everything he had taken, suffered from constipation and had a terrible headache. I found him in bed, apparently ill; his face was pale with a tinge of gray and there was some degree of apathy but no cyanosis or dyspnea. His temperature was normal. The tongue was slightly coated. There was no specific fetor. The lungs were normal. The heart was enlarged to the left one fingerbreadth. The apex beat was markedly accentuated. There were no murmurs. The pulse rate was 80; the pulse was regular and equal. The blood pressure was 215 systolic, 155 diastolic, 260/155 and higher than 260, although the patient did not move. The abdomen was normal; there was no ascites. The extremities were normal. There was no edema. The reflexes and pupils were normal. Except for an enema, I did not suggest any medication or food intake. On the following day he felt somewhat better. I took about 60 cc. of blood. The blood and the urine were tested. Nonprotein nitrogen was 25.2 mg., urea nitrogen 12 mg. The urine contained a heavy deposit of albumin; its color was light amber; it was acid in reaction and the specific gravity was 1.019. There were no traces of sugar or acetone. Hyaline, finely, coarsely granular and pus casts numbered 40 to 50 per field (one-fourth inch objective), red blood cells 60 to 75 per field, white cells 100 to 125, and there were a few flat and renal epithelial cells, a large amount of mucus, and amorphous urates. The Wassermann and Kahn tests were negative. To be on the safe side, I gave the patient a vegetarian, salt-free diet with plenty of potatoes, as though to combat "acidosis." His condition improved. He is no more in a stage of apathy. His appetite is improving. He has not vomited since. Two days ago I took blood again (about 100 cc., as for some reason I could not take from 200 to 250 cc., as intended). The patient stated on this occasion again that he felt some relief soon after that, especially in the head. As he cannot stand the sight of blood, he almost faints. The blood pressure is then lower, about 170/120, but naturally goes up again as soon as the patient regains full consciousness. At the last phlebotomy the diastolic pressure dropped for the first time to 130 and remained as low. There seems to be no renal insufficiency, as the intake of fluid (restricted to one quart) equals almost the output. There is no nocturia. The symptoms pointed to uremia. What puzzled me and still is puzzling me is that uremic symptoms should occur while the nonprotein nitrogen and urea nitrogen were normal the day after. I was thinking of nephrosclerosis, although the high amount of albumin is mostly not found in this disease. On the other hand, malignant nephrosis does not fit into the picture either. Would you kindly advise me as to the diagnosis and outline a treatment; namely, whether it is advisable to add salt to the diet and by what means I should try to lower the blood pressure and what to do to make the albumin disappear gradually? Please omit name. M.D., New York.

ANSWER.—The clinical picture described of marked arterial hypertension, cardiac hypertrophy and severe headaches in a man of 46 suggests inclusion in the group designated "malignant hypertension," because of its grave prognosis. Examination of the eyegrounds might furnish information of value. Whereas the condition may have originated as an essential hypertension, it has evidently progressed to an arteriosclerosis. The kidneys are evidently involved to some extent, but the absence of nitrogen retention speaks against uremia as the cause of the recent accident. There remains to rule out a cardiac or cerebral accident. Coronary sclerosis with occlusion of a small branch has not been entirely ruled out although the pulse rate was normal, dyspnea absent and the blood pressure high. An electrocardiogram would be of value. A cerebral accident seems most likely in view of the preceding headaches and relief when the high blood pressure was lowered. As regards treatment, prolonged bed rest and adequate venesection seem clearly indicated. A balanced diet with sufficient protein to meet his

This single finding ought not to be considered of any general significance, for it by no means proves that the user of public telephones runs the risk of becoming infected. It should also be kept in mind that for the purpose of these examinations the layers of dirt underwent a much more thorough process of removal and collection together than would ever take place under ordinary circumstances. Professor Lange concludes from his investigations that there exists no real danger of infection from the use of a telephone.

### ITALY

(From Our Regular Correspondent)

Nov. 15, 1936.

#### National Congress of Surgery

The forty-third National Congress of Surgery, which was organized by the Società Italiana di Chirurgia with the collaboration of all the directors of the surgical clinics of the Italian universities, the general directors of health and sanitation of the army and the navy and many foreign surgeons, took place recently in Rome. Professor Grant of Philadelphia was also present.

The first official topic was trauma of the spinal column. Professors Donati and Lapidari of Milan spoke on fractures of the spine and osteo-articular lesions from trauma. The frequency of spinal fractures depends on the improvement of the diagnosis rather than in an actual increase of fractures. The conditions of the spine should be verified by means of x-ray examination of the structure (at least in the anteroposterior and lateral views) in all cases of spinal trauma, because of the fact that by ignoring the nature of the vertebral lesion and giving the patient erroneous or insufficient treatment there may develop secondary functional or anatomic alterations of the spine. Total fractures, as a rule, are caused by an indirect mechanism, especially by compression in hyperflexion of the spine. Compression in hyperextension of the spine, crushing, squashing and torsion are also causes of total fractures. Partial fractures involving the spinous and transverse apophyses and sometimes the vertebral arches may be caused by an indirect mechanism. The lesions of the vertebral bodies caused by muscular contracture in tetanus induce structural changes in the spongy tissues of the vertebra. Complete anterior luxation of the atlas is rare. It causes death by compressing the spinal cord within the posterior vertebral arch and the odontoid vertebra. The fracture of the odontoid process of the second cervical vertebra is grave if it complicates anterior luxation of the atlas. The odontoid process has a tendency not to consolidate to the vertebra after a fracture. For this reason it is necessary to verify the consolidation of the process to the vertebra, by means of x-ray examination of the latter before immobilization is discontinued. The fifth cervical vertebra also is frequently fractured. The fracture is caused by an indirect mechanism. It is frequent in persons who dive into shallow water. The treatment of selection is reduction of the fracture by continuous traction with the patient in bed. Laminectomy fails in giving satisfactory results. If the symptoms given by the spinal cord are due to hematomyelia or to edema of the spinal cord they are resolved by themselves, regardless of performing or not doing a laminectomy. In cases of lesions already established in the neuro-axis, the conditions of the patient are aggravated by a laminectomy. Fractures of the dorsolumbar segment involve frequently the twelfth dorsal and the first lumbar vertebra. They are induced by an indirect mechanism and by compression. The lesions of the intervertebral disks are characteristic. The treatment of preference is immediate reduction of the lesion and immobilization. In order to give the patient general anesthesia, he is placed on a suspension hammock which determines hyperextension of the spine with the patient in the supine position. Orthopedic surgery is indicated in fractures of the vertebral arches, laminae and pedunculi.

Professor Antonucci of Milan spoke on the lesions of the spinal cord and of the roots of the spinal nerves from trauma of the spinal column. According to the speaker, orthopedic surgery in association with systematic lumbar and cisternal punctures (for preventing blockage of the cerebrospinal fluid) is indicated in cases of medullary lesions from trauma. In open lesions of the spinal cord the treatment should preferably be surgical, consisting in cleansing the wound and performing a laminectomy. Suturing the spinal cord should be avoided. The attempts of treating complete transverse section of the lumbosacral spinal cord by interradicular or intercostoradicular anastomoses, according to Antonucci's technic, should be studied by experiments and be used in cases of this nature.

The second official topic was "Surgery of Cranial Nerve." Professors Fasiani and Belloni of the University of Padua spoke on surgery of the intracerebral optic tract. They discussed the diseases of the optic segment which is included within the optic canal and the primary optic nerves, for the surgical approach to which the cranium has to be opened. Tumors of the optic nerve and of the optic chiasm are rare. More frequent than the latter are tumors of the sella turcica and of the parasellar region with visual symptoms. The speakers gave a classification of these tumors. They described also a technic for examination of the optic chiasm area as well as for the opening of the optic canal by the intracranial and orbital routes of approach.

Professor Dogliotti of Modena University spoke on surgery of the facial and trigeminal nerves. In treating trigeminal neuralgia the peripheral operations (alcoholization and section of the external branches) was followed by central operation first on the gasserian ganglion and then on the retroganglionic roots, and on the temporal and pontile-petrous tracts. Operations on the gasserian ganglion are alcoholization, electrocoagulation and gasserectomy. The operations on the retroganglionic routes may be made by the temporal route (Frazier's technic), the cerebellar route (Dandy's technic) or the supratentorial occipital route (Dogliotto's technic). In the latter the route of approach is a supratentorial retro-auricular craniotomy. In sectioning the root of the trigeminal nerve (which is easily identified when the occipital lobe is raised and the cerebellum is slightly displaced) the motor root is easily left untouched. The speaker advises partial neurotomy with removal of two thirds or three fourths of the root in order to preserve a part of the sensitivity of the face and especially of the cornea and the conjunctiva. Professor Dogliotti discussed surgery of peripheral paralysis and essential spasms of the facial nerve. In traumatic paralysis by total section of the nerve it is advisable to perform an early or immediate operation. In all the other forms of peripheral paralysis it is advisable to give the patient several of the direct and indirect causal treatments for some months and then resort to operation. Resection of the nerve with freshening of the stumps and implantation of a nerve graft in the stumps of the resected nerve (Ballace and Duel operation) is indicated. In essential spasms of the facial nerve, blockage of the nerve with alcohol or by electrocoagulation, partial neurotomy, nervous grafts and plastic operations are indicated. Up to now none of the technics have given permanent satisfactory results, unless the functions of the nerve are sacrificed. The speaker reported satisfactory results from a technic which consists in sectioning the nerve, removal of about half of the central stump and neurotization of the peripheral branches by means of the residual portion of the central stump.

The next congress will meet at Turin. The following will be the official topics: (1) tumors of the sella turcica and parasellar area, (2) indications and late results of removal of calculi of urinary tract, and (3) late results of operation of gastroduodenal and jejunal ulcers.

should be increased 1 F. weekly, provided no undue trauma has been produced by the preceding instrumentation.

If a 26 F. cannot pass the meatus, a urethral meatotomy should be performed and the dilatation increased to from 28 to 32 F.

No more vaccines should be given.

For treatment at home the patient should inject the anterior urethra with 5 cc. of a 5 per cent neosilvol solution twice daily. When the smears and shreds have become negative, the treatment should be tapered off and the condition provoked with silver nitrate beginning with 0.125 per cent increasing to 0.25 per cent. If smears remain negative for from six to twelve months with checks at intervals of from three to six weeks, cure probably has occurred.

#### HYPERPERISTALSIS WITH BORBORYGMUS

To the Editor:—I have had under observation for the past several years an intelligent young business executive whose chief complaint is indigestion and flatulence. After thorough physical examination, together with laboratory work and a gastro-intestinal series, revealed nothing abnormal, a diagnosis of nervous indigestion was made. The underlying condition was explained to him and he was given appropriate matter on the subject to read. With an excellent insight into the subject he adjusted himself well, performing his work efficiently despite his handicap. Recently, ignoring my advice, he accepted a better position with another firm entailing many more responsibilities than he formerly had and after a period of about six months, when he felt he was becoming well adjusted to his new work, hyperperistalsis of the small intestine set in with resultant loud rumbling and gurgling sounds emanating from the abdomen. After a meal this condition would begin and continue almost until the time for the next meal, when the process would be repeated. He learned to control it somewhat by eating small meals, but there was a resultant loss of weight. He is now back at his original position, but after a year the syndrome of hyperperistalsis is still dominant, although diminished somewhat in intensity. Reexamination, together with basal metabolic rate determinations, laboratory work and a gastro-intestinal series, shows nothing of significance. His home life is ideal and he has no financial worries. He is clamoring for relief not from any subjective symptoms, to which he has become inured, but from the embarrassing sounds induced by the hyperperistalsis, which greatly hinder his efficiency and usefulness and prevent him from making the contacts he would like. Sedatives are of no avail, for enough to cause drowsiness must be taken before the abdominal condition is controlled. I have tried atropine and the newer synthetic preparations said to be useful in relaxing smooth muscle, but all have proved of little value. Various types of diet have been resorted to without much success. His appetite is good, as is his general condition. Consultants agree as to the cause but have not been able to offer suggestions of any great value. What is the possibility of this condition clearing up as far as the hyperperistalsis syndrome is concerned? Am I justified in recommending splanchnic resection in a case of this type, in which the exaggerated gastro-intestinal behavior dominates the picture to the exclusion of all else? I would appreciate any suggestions as to prognosis and treatment. Please omit name.

M.D., Louisiana.

ANSWER.—There can be little question about the functional nature of the trouble, especially when the symptoms run on for a year or more. One can then exclude an obstructing lesion in the small intestine, because persons with such lesions are generally forced to operation within six months. As the correspondent says, the difficulty comes when one tries to cure the condition. Theoretically the prescription most likely to give results would be one for a long vacation. With these cases, drugs and diets are of little avail. Even fasting cannot help much, because in both animals and men the activity of the empty bowel is sometimes even more boisterous than that of the digesting bowel, much as the gastric hunger activity is often more striking than that seen when the stomach is full.

Section of the splanchnic nerves is contraindicated because in both animals and man it is likely to be followed at least for a time by increased activity of the bowel. After double splanchnicotomy the rabbit usually dies of diarrhea and inanition, but cats, dogs and men are better able to stand the release of inhibition which comes with degeneration of the sympathetic nerves.

One can hardly hope to quiet the gurgling bowel by removing nervous influences because of the experiences of men like Sinelnikoff who, in the case of a young woman who had swallowed lye, transplanted a piece of jejunum out under the skin of the chest so that it could be used as an esophagus. Two years later the rhythmic contractions of this denervated segment were even more powerful than they were to begin with. Actually, what seems to be needed by the persons with an overactive bowel is more nervous control rather than less.

In one case, intestinal gurgling became so distressing and painful during the course of several years that the patient was disabled. Two explorations of the abdomen revealed no cause for the trouble. Because the trouble was limited to the right side of the abdomen and because it had resulted in such disablement, the attending physicians in desperation had the three

right splanchnic nerves sectioned and the first and second lumbar sympathetic ganglions removed. The patient is somewhat worse, and the probability is now that section of the nerves on the other side would make her worse yet. In this patient there are several signs of Cushing's basophilic syndrome but it is hard to say what this has to do with the rumbling. At the time of exploration the right adrenal gland was found to be normal. It is probable that the severe disturbance in the glands of internal secretion is responsible for the nervous condition of the patient, which again may well be responsible for the overactive and oversensitive bowel; but the gurgling disease is so rare that no one can yet say what belongs in the syndrome and what doesn't.

The prognosis is not hopeful, because some of these people tend to get worse as years pass, especially if they cannot afford to take the long rest which alone will tone up the nervous system.

To make certain that there is no causative element in the diet, it might be well to keep the patient for two or three days on nothing but maple sugar, or perhaps lamb and rice, to see if here is any improvement. In one case the patient, a physician, discovered that blackberry cordial would give relief. In some cases the patient is helped if, before going out to dinner or to some function where he wishes to be on his good behavior, he takes 0.03 Gm. (one-half grain) of codeine sulfate. Another drug that might perhaps be tried is the supposed sympathetic sedative ergotamine tartrate (to be used only occasionally). According to recent papers by Cannon and Rosenblueth, yohimbine and piperidinomethyl benzodioxane (see a series of papers published in 1936 by Bovet and others from the Pasteur Institute) are the best two drugs with which to block the effects of stimulating sympathetic nerves. Theoretically, however, to quiet the bowel one should give a sympathetic stimulant or mimetic, the most powerful being epinephrine; but the action of this drug is transient and is likely to be followed by excess activity of the bowel. A more prolonged stimulation might perhaps be obtained with benzedrine.

In some of these cases of gurgling the physician must wonder whether the borborygmus is any worse or more noisy than that present in many uncomplaining persons. In such cases the trouble is probably due to the same type of hypersensitiveness or abnormal awareness of normal bodily functions that causes persons to complain of the heart beat or of floating specks before the eyes. Obviously, in such cases the treatment must consist of reassurance and very tactful argument.

#### SWELLING OF THE LEGS

To the Editor:—I have a patient who first consulted me a few days ago with bilateral swelling of the legs, particularly from the knees to the ankles. The condition has been present for twelve years. She is now 32 years of age. She was recently married and has had only one pregnancy, which was uneventful. The child is nearly 2 years old. The legs are slim and natural in the mornings but are much worse at night; they were better during her pregnancy, however. The patient suffers from constipation but complains of no other symptom except a heavy weighted feeling in the lower part of the legs. The blood pressure is 125 systolic, 80 diastolic. The heart is normal. Can you give me any suggestions as to the cause and treatment of such a case? I have been treating the constipation for just a few days so far; and have advised Ace bandages as a temporary support. These, however, make deep impressions in the leg by bedtime. Thank you for your help; if this should be put in THE JOURNAL, please omit name.

M.D., District of Columbia.

ANSWER.—In general there are four kinds of diffuse swellings of the lower extremities: (1) that resulting from disturbed function of distant organs, such as diseases of the heart and kidneys; (2) that due to impaired lymphatic circulation; (3) that due to impaired venous circulation, and (4) that associated with excessive adiposity. The early history of the swelling is important in arriving at the diagnosis. One needs to know whether or not the swelling began simultaneously in the two legs, whether or not it came on suddenly, and whether or not it was associated with pain or fever. It is important likewise to know whether or not there is excess adipose tissue in the lower extremities and whether or not varicose veins are present. A good deal of help from a diagnostic standpoint can be obtained by observing the texture of the skin. In lymphedema it ordinarily loses its smooth texture. In the case under consideration it is probable that the swelling came on simultaneously in the two extremities and was not associated with pain or fever. If disease of the heart and kidneys and hypoproteinemia have been excluded, the swelling is probably associated with excessive adiposity of the lower extremities or due to impaired lymphatic circulation. If the edema can be demar-

## Deaths

**Roy Hayman McKay** ☉ Miami, Fla.; Medical College of Ohio, Cincinnati, 1906; formerly a practitioner in Akron, Ohio; past president of the Summit County (Ohio) Medical Society; fellow of the American College of Surgeons; at various times on the staffs of the People's Hospital, Children's Hospital and City Hospital, Akron, and the Citizens Hospital, Barberton; served during the World War; co-author of "Let's Operate"; aged 53; died, Nov. 28, 1936, in a local hospital, of injuries received in a fall.

**Harry Feld Mather**, Kansas City, Mo.; University Medical College of Kansas City, 1895; member of the Missouri State Medical Association; at one time assistant professor of anatomy and assistant to the chair of surgery at his alma mater; formerly on the staffs of St. Luke's, St. Joseph, Menorah and Research hospitals; medical director of the Midland Life Insurance Company; aged 64; died, Nov. 23, 1936, of cerebral hemorrhage.

**Thomas DeWitt Gordon** ☉ Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1909; member of the American Academy of Pediatrics; fellow of the American College of Physicians; past president of the Kent County Medical Society; served during the World War; on the staff of the Blodgett Memorial Hospital; aged 56; died, Nov. 20, 1936, of coronary thrombosis.

**Frank Paul Pettey**, Decatur, Ala.; University of Nashville (Tenn.) Medical Department, 1892; member of the Medical Association of the State of Alabama; past president of the Morgan County Medical Society; was president of the county board of health; served during the World War; aged 69; died, Nov. 26, 1936, in the Wallace Sanitarium, Memphis, Tenn.

**Malcolm Newlon**, Lincoln, Kan.; University Medical College of Kansas City, 1910; member of the Kansas Medical Society; secretary of the Lincoln County Medical Society; served during the World War; formerly member of the city council and health officer; chairman of the school board; aged 50; died, Nov. 18, 1936, in St. John's Hospital, Salina.

**Alva J. Weedn** ☉ Duncan, Okla.; Central University of Medicine and Science, Jersey City, N. J., 1901; past president of the Stephens County Medical Society; formerly secretary of the Oklahoma Hospital Association; president emeritus of the Southern Oklahoma Medical Association; owner of a hospital bearing his name; aged 61; died, Nov. 15, 1936.

**Charles Dickinson Phelps**, West Haven, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Connecticut State Medical Society; at one time instructor in physical diagnosis at Yale University School of Medicine, New Haven; aged 68; died, Nov. 24, 1936, of chronic myocarditis.

**John George O'Meara** ☉ Providence, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; formerly member of the state legislature; aged 68; member of the staffs of the Homeopathic Hospital and St. Joseph's Hospital, where he died, Nov. 22, 1936, of carcinoma of the head of the pancreas with metastasis to the liver.

**Benjamin Thomas Sharp** ☉ Kansas City, Mo.; St. Louis College of Physicians and Surgeons, 1897; aged 62; member of the staffs of the Research Hospital, Menorah Hospital and St. Mary's Hospital, where he died, Nov. 30, 1936, of pneumonia, following a hip fracture received in a fall.

**George Everett Tucker**, Salem, Mass.; Medical School of Maine, Portland, 1908; member of the Massachusetts Medical Society; physician for the city schools; aged 53; on the staff of the Salem Hospital, where he died, Nov. 30, 1936, of arteriosclerosis and cerebral hemorrhage.

**Noe Franklin Chostner**, Cape Girardeau, Mo.; St. Louis College of Physicians and Surgeons, 1905; member of the Missouri State Medical Association; on the staffs of the Southeast Missouri Hospital and St. Francis Hospital; aged 56; died, Nov. 13, 1936, of heart disease.

**William J. Kellow**, Watertown, N. Y.; Victoria University Medical Department, Coburg, Ont., Canada, 1882; for many years on the staffs of the House of the Good Samaritan and the Mercy Hospital; aged 77; died, Nov. 23, 1936, in St. Petersburg, Fla., of uremia.

**Albert Schloemilch**, Portage, Wis.; Hahnemann Medical College and Hospital, Chicago, 1875; member of the State Medical Society of Wisconsin; aged 82; on the staff of St. Saviors General Hospital, where he died, Nov. 15, 1936, of acute enteritis.

**George Clarkson Worth**, Kiangyin, Kiangsu, China; University of Virginia Department of Medicine, Charlottesville, 1892; medical missionary of the Presbyterian Church in China; stationed at the Kiangyin Christian Hospital; aged 69; died recently.

**Milton Jefferson Moore** ☉ Vernon, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1914; formerly member of the school board; part owner of a hospital bearing his name; aged 47; died, Nov. 17, 1936, of angina pectoris.

**John Frederick Shaw**, Fairfield, Maine; University of Toronto (Ont.) Faculty of Medicine, 1914; member of the Maine Medical Association; superintendent of the Central Maine Sanitarium; aged 47; died, Nov. 22, 1936, of cardiac asthma.

**Thompson R. Terwilliger**, Lima, Ohio; Medical College of Ohio, Cincinnati, 1887; member of the Ohio State Medical Association; member of the staffs of St. Rita's and Memorial hospitals; aged 75; died, Nov. 26, 1936, in a hospital at Cincinnati.

**James Elmer Wright** ☉ Rochester, N. Y.; University of Buffalo School of Medicine, 1913; served during the World War; aged 48; on the staff of the Rochester General Hospital, where he died, Nov. 24, 1936, of dissecting aneurysm of the aorta.

**Peter John Christofferson** ☉ Waupaca, Wis.; Marion-Sims College of Medicine, St. Louis, 1897; past president of the Waupaca County Medical Society; aged 67; part owner of the Waupaca Hospital and Clinic, where he died, Nov. 27, 1936.

**Charles Atwell Kearney**, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1898; served during the World War; member of the staff of the Veterans Administration Facility; aged 68; died, Nov. 19, 1936, in Iowa City.

**Luther Asbury De Loach** ☉ Savannah, Ga.; Atlanta College of Physicians and Surgeons, 1905; formerly mayor of Glennville; on the staff of the Warren A. Candler Hospital; aged 53; died, Nov. 22, 1936, of angina pectoris.

**Herschel Charlton Ezell** ☉ Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1911; member of the American Academy of Ophthalmology and Otolaryngology; aged 48; died, Nov. 26, 1936.

**Edwin Parker Pitman**, New Haven, Conn.; Dartmouth Medical School, Hanover, N. H., 1891; member of the Connecticut State Medical Society; aged 73; died, Nov. 25, 1936, of prostatic hypertrophy and hydronephrosis.

**William Buckman Holcombe**, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1895; aged 62; died, Nov. 24, 1936, in the Hahnemann Hospital, of adenocarcinoma of the cecum and ascending colon.

**Elmer E. Kirk**, Newcastle, Ind.; Cincinnati College of Medicine and Surgery, 1888; member of the Indiana State Medical Association; aged 74; on the staff of the Henry County Hospital, where he died, Nov. 13, 1936.

**Sarah Mann Wilbur**, Springfield, Mass.; Woman's Medical College of Pennsylvania, Philadelphia, 1885; member of the Massachusetts and Rhode Island medical societies; aged 83; died, Nov. 20, 1936, of chronic nephritis.

**Monte A. Stern** ☉ Sioux Falls, S. D.; John A. Creighton Medical College, Omaha, 1908; fellow of the American College of Surgeons; on the staffs of the Sioux Valley and McKennan hospitals; aged 51; died, Nov. 8, 1936.

**Charles Himes Metzel**, Sidney, Ill.; University of Illinois College of Medicine, Chicago, 1931; member of the Illinois State Medical Society; on the staff of the Mercy Hospital, Urbana; aged 31; died, Nov. 20, 1936.

**Jeptha Jonson Thibault**, Atlanta, Ga.; University of Arkansas School of Medicine, Little Rock, 1936; aged 24; intern at the Piedmont Hospital, where he died, Nov. 19, 1936, of a Streptococcus viridans infection.

**Frank Cornwall McTavish**, Vancouver, B. C., Canada; University of Toronto Faculty of Medicine, 1899; L.S.A., London, 1901; L.R.C.P., London, and M.R.C.S., England, 1903; aged 64; died, Nov. 8, 1936.

**Robert Haldane Mitchell**, Bowie, Texas; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1883; aged 75; died, Nov. 17, 1936, in the Bowie Clinic Hospital, of gallbladder disease.

the prostatic infection persists in spite of thorough treatment, intraprostatic injection of antiseptic solutions such as mercurochrome might be considered.

#### HEMOLYTIC JAUNDICE IN PREGNANCY

*To the Editor:*—A woman, aged 22, height 66 inches (167 cm.), weight 130 pounds (59 Kg.), with no history of previous illnesses and of excellent physical type, has had a normal pregnancy for eight months. Pain over the gallbladder began Jan. 1, 1936, and has increased in intensity with no relief except narcotics. Albumin in the urine was detected January 15, with hypertension. She was taken to a hospital for observation. Jaundice developed. There were no convulsions. January 20 a normal delivery occurred. Six hours later there were all the symptoms of a severe hemorrhage. The patient was almost moribund, with no bleeding and a firm uterus. Blood count revealed 1,500,000 red cells, 11,000 white cells and hemoglobin 30 per cent. The jaundice had cleared, but the diagnosis in retrospect specified the hemolytic form. Two full sisters, who are living and well, have never been pregnant; one half sister on the paternal side with two children and one half sister on the paternal side died with eclampsia and jaundice; one aunt on the paternal side died with eclampsia, the jaundice condition unknown. There is no other pertinent family history. The patient is now again pregnant with March 13 as the date of the last period. She asks for the best advice. She is anxious for a child if it is best to carry on. I have never before had hemolytic jaundice with pregnancy and request information as to the likelihood of recurrence in successive pregnancies from the history of similar cases. Her condition now is excellent. The former infant died February 2 from apparent toxemia. Please advise me what is best to do. M.D., Iowa.

**ANSWER.**—Hemolytic jaundice is extremely rare in pregnant women, and when it occurs it is usually linked up with the toxemias of pregnancy, although the exact etiology is unknown. The family history in the present case points to a tendency for the relatives on the paternal side to develop toxemia during pregnancy. Nearly all attacks of hemolytic jaundice are serious, some critical and a few fatal. It is difficult to prognosticate what will happen in the present case. Attacks of hemolytic jaundice frequently recur. An important factor to consider is that the disease may be transmitted to the baby. Perhaps the first child died of the disease a few days after birth. In view of these facts, it may properly be suggested to the patient and her husband that the present pregnancy be interrupted, provided the diagnosis of hemolytic jaundice is correct in the present case.

#### DIFFERENTIAL DIAGNOSIS OF GASTRO-INTESTINAL CONDITION

*To the Editor:*—A single woman, aged 22, complains of the following symptoms extending over a period of two years. The condition is much more pronounced in the summer and she goes three or four months in the winter free from trouble. In the early morning she usually wakes with a gnawing in her stomach. Immediately after breakfast she has pain in the abdomen followed by from one to four yellowish watery stools. Her description is that she gets no relief until her breakfast passes from the body. Sometimes these stools are not associated with pain. The stools are watery, sometimes lumpy, with no marked odor. Diet does not affect the condition. She has been on diluted hydrochloric acid, camphorated tincture of opium and emetine hydrochloride, hypodermically at different intervals with no relief. Thank you for any suggestions you have to offer. M.D., North Carolina.

**ANSWER.**—It is difficult to make much of a guess as to the nature of this woman's difficulty, and the diagnosis might be just as obscure after one had made the most careful study possible of the digestive tract and the stools. Years ago, with such a story, one would think first of an achlorhydria, but it is known now that achlorhydric diarrheas are rather rare, and this patient has not responded to the giving of acid.

It would be well to have the stools searched for parasites by an expert. It is possible that she has a chronic infection with one of the several organisms that can produce a recurrent dysentery.

Both the small intestine and the colon should be examined with x-rays and the patient should have a sigmoidoscopic examination to make sure that there are no signs of ulceration in the lower bowel. It would be interesting to see if there is free acid in the stomach. If there is some, that will also help to rule out a beginning pernicious anemia.

We assume that the patient has not at any time submitted to gastro-enterostomy or to any abdominal operation supposed to be a gastro-enterostomy.

It would be well to see whether the patient is sensitive to certain foods. The fact that the trouble comes in summer suggests that she is sensitive to one or more fruits. She might stay for a while on the type of diet which she follows in the winter. If that should bring relief, the offending foods could easily be discovered by testing one at a time.

The supper incidence suggests also that she is sensitive to bacteria that multiply in milk, ice cream, meat (especially hamburger steak) and other foods in hot weather.

Emotional causes for diarrhea must never be forgotten, nor must it be forgotten that the milk given by way of treatment may be a cause. An elimination diet of lamb and rice might be tried for a few days to see if it brings relief. One might try the giving of calcium gluconate, also a low-fat diet.

#### PRIAPISM

*To the Editor:*—I have a patient 60 years of age, in good health, with complaints of uncomfortable penile erections, which appear each night at about 3 a. m. They always wake him and he can obtain relief only by assuming certain postures. He states that he loses from one to two hours sleep and feels exhausted afterward. These symptoms appeared gradually about four years ago. He thinks that their origin may be in some way connected with an extramarital liaison which existed at about this time with a woman who was almost pathologically libidinous. This relation existed for several months. About two years ago he had an endoscopic resection of his prostate at a large clinic for the relief of mild prostatism, which had existed for several months. This operation relieved retention but in no way affected the erections. He states that he had gonorrhea in his youth and has been told that he had a stricture. When he came to me he stated that he feared that in some way his trouble might lead to insanity. He exhibits no other neurotic traits. His libido is normal. Physical examination is negative. When first seen he had a mild posterior urethritis, a rather small meatus and a posterior urethral stricture of large caliber. Treatment has consisted of topical applications of silver nitrate through the endoscope, sounds, meatotomy and instillations of silver nitrate to the posterior urethra. Although the urethritis has practically cleared up, there has been no change in his symptoms. He states that he is no longer worried about himself, thanks to my reassurance as to his mental state, but he is otherwise no better. What to do? All available literature deals at length with frank priapism but gives little light on this particular condition. He says he would not at present consent to any measure that would incapacitate him sexually. Please omit name. M.D., Oklahoma.

**ANSWER.**—Cases similar to the one presented will be found in an article published in the *Medical Journal and Record*, Dec. 3, 1930, page 521, by Max Huhner under the title of "Some Unusual Cases of Priapism." The condition is not serious unless of course due to cerebral or spinal disturbance or to leukemia or some similar condition. It may be that the extramarital liaison, especially if accompanied by ungratified sexual excitement, might have been the starting point of the condition. In the absence of any pathologic condition he should be treated by gentle massage of the prostate and instillations of weak (1:3,000-1:500) silver nitrate solutions into the prostatic urethra. If after two months of this treatment no result is obtained, epidural injections of either plain sterile saline solution or procaine hydrochloride combined with saline solution (procaine 10 cc., saline solution 80 cc.) may be given at intervals of a week, and generally after three such injections relief is obtained. Neither of these procedures interferes with sexual capacity.

#### TREATMENT OF ENLARGED PROSTATE AND NONMOTILE SPERM

*To the Editor:*—A man, aged 32, married ten years, without children, whose general health is good, has had a satisfactory sexual life, with normal intercourse and normal discharge. He had gonorrhea when 19, which he says was mild and from which he recovered in a short time. He had an acute attack of "bladder trouble" about a year ago and had to be catheterized for about a week. On rectal examination I find a markedly enlarged prostate, which I would consider 3 plus. The seminal vesicles are very much enlarged and very sensitive. I have been massaging the prostate biweekly for about a month and it is not improving very fast, although he says he has a marked feeling of relief and that he urinates with greater ease and much more freely. The real reason for his coming to me was to see why his wife did not become pregnant. I have made three microscopic examinations of fresh sperm and find no motile sperm in any of them. What I should like to know is what can be done with the prostate as far as the enlargement is concerned and also if there is any chance for his sperm to become normal if the prostate improves. Please answer fully. M.D., Iowa.

**ANSWER.**—In the description of this case nothing stated is as to the type of material obtained by massage: whether pus is present or not. If the enormous enlargement of the prostate gland as described is due to infection, pus should be drained at each stripping. Again, the determination of the motility of the sperm depends much on the method used at examination. If the enlargement is due to infection and this is cleared up by massage, it is possible that active sperm may be found; however, the pathologic nature of the enlargement should be determined in this case by a urologic study.

## Bureau of Investigation

LINDEN RAY EMERICK, M.D.

### The Postmaster General Closes the Mails to a Diabetes Fraud

On Dec. 7, 1936, the Postmaster General closed the mails to L. R. Emerick, M.D., of Eaton, Ohio, operating a mail-order "cure" for diabetes under the following trade names: Dr. L. Emerick, Dr. Emerick, L. Emerick, L. R. Emerick, M.D., and L. R. Emerick.

Years ago L. R. Emerick was selling a booklet entitled "Dr. Emerick's Tried and Proven Formulas." The booklet was a hodge-podge of formulas for various ailments, beginning with asthma and ending with a mixture "For White Diarrhoea for Chicken," with "A Dandy Ice Cream Recipe" and "The Best for Roop" thrown in for good measure.

The Emerick treatment for "Diabetes," as given in the "Tried and Proven Formulas" (1922), consisted of tablets containing "Syngium Jamb., 2 Gr.; Phosphoric Acid, 1-100 Gr.; Ferrum Arsen., 1-100 Gr." The instructions were: "Give one or two, 3 or 4 times a day, with avoidance by patient of foods containing starch and sugar, will certainly give wonderful results. I have cleared up every case, but one, who was too far gone when seen. This is worth \$10 to any Dr." Just what Emerick thought his nostrum worth to the patient, he neglected to say.

Emerick secured his clientele by means of advertisements, and written and printed matter sent through the mails. One of the advertisements used by Emerick reads as follows:

#### "I HAD DIABETES MYSELF

Now enjoy the best of health, eat everything. I have successfully treated it for fifteen years. Readers of this magazine are invited to write for FREE particulars, to

DR. L. EMERICK

224 N. Barron Street

Eaton, Ohio

MENTION MAIL ORDER TABLOID WHEN WRITING"

If the unfortunate victim of diabetes had his curiosity sufficiently aroused to respond to the advertising "bait," he received a mimeographed form-letter reading in part as follows:

"I am glad of the opportunity to write you, for since I had Diabetes myself I can fully sympathize with one so afflicted. I am surely glad to have gotten rid of it, also glad I can help others back to the health I enjoy. For I enjoy the best of health, and have for over sixteen years. And eat everything.

"I wish to be honest with you, and will say that if you have used Insulin for several months, especially in heavy doses, you just as well go on using it. As it has been my experience that it is almost impossible to get off it. However if you have never used it, or using light doses; my treatment should prove a great blessing to you. As it has to myself, and many others some of whose testimony I am enclosing. . . .

"I am sure I can assure you help. I treat by the month, charging ten dollars a month, and I include any extra medicines needed. Most cases need something for the nerves, liver, weakness, and pain somewhere, until they get started . . ."

Dr. Emerick was not to be denied, once given a nibble. If the diabetic hesitated in parting with his cash, he received form-letter number two:

"Recently you wrote me asking about my Diabetic treatment. I sent you information of same, with some evidence of its effectiveness, and I do not understand why I have not heard from you. Surely you want to get rid of the malady . . .

"So fill out the pink slip I sent you, and let us get you started back to health. I have never had any who have regretted having taken the treatment, and I do not believe you would.

"Your health is at stake . . ."

Emerick further supplemented his follow-up letters with a partial biography of his life:

"A few words about myself—a practicing physician in Ohio for over thirty years—a graduate in 1902 from Hospital College of Medicine, Louisville, Ky.

"I, myself broke down with Diabetes and in May, 1916, had to discontinue my work and was not able to get back to my practice until August, 1918. . . .

"I appealed for help to a number of prominent physicians throughout the country without receiving any benefit or much encouragement . . .

"From the literature I gathered and by many experiments upon myself, I evolved THE REMEDY that has completely relieved me as evidenced by my coming back into practice in October, 1918, and going thru that great EPIDEMIC OF FLU . . .

"In searching medical literature I found where an old German doctor [Ye Gods! The old German doctor again!] who had been experimenting on Diabetes stated a short time before his death that he believed that if a certain preparation was given in large enough doses, that it would prove a specific in relieving Diabetes. . . ."

The treatment, according to the formula furnished by Emerick to the United States post office authorities, consisted of several packages of tablets, one marked for diabetes, the others varying according to the symptoms furnished by the patient on the "pink slip."

The alleged diabetic tablets were composed of jambul seed, 10 grains, phosphoric acid,  $\frac{1}{100}$  grain, and iron arsenate,  $\frac{1}{100}$  grain. Directions provided for the taking of two of these tablets before meals. The tablets "for weakness," according to the analysis of the Food and Drug Administration of the United States Department of Agriculture, contained strychnine sulfate,  $\frac{1}{100}$  grain per tablet, with sugar, starch and carbonate present. The tablets "for aching" contained 4.9 grains of sodium salicylate per tablet, mixed with a small amount of starch and talc. The tablets "for liver" contained  $\frac{1}{100}$  grain strychnine sulfate and  $\frac{1}{2}$  grain phenolphthalein per tablet, with podophyllum and aloes present, and the tablets "for nerves" contained the fetish asafetida with magnesia and sugar present. In addition to the auxiliary tablets, Emerick furnished a so-called "Diabetic Diet."

Medical experts introduced by the government declared the Emerick "treatment" to be a haphazard collection of sedatives, stimulants and laxatives. They further pointed out that the drugs making up the "treatment" have long been known to the medical profession and have been thoroughly tested, discredited and discarded as worthless in the treatment of diabetes.

Emerick, in answer to the charges filed by Solicitor Karl A. Crowley, related a series of instances in which he alleged cures had been obtained by the use of his "treatment." In his report the Solicitor stated: "The expert evidence shows, and I do so find, that these alleged cures cannot actually have occurred."

Although Emerick advocated "To base my expectations of reward on a solid foundation of service rendered. To be willing to pay the price of success in honest effort," Post Office Solicitor Crowley recommended that a fraud order be issued against Emerick and the various names under which he sold his diabetes "cure." It was so issued.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### MOSHER PARAFFIN BASKET FOR SKIN GRAFT AFTER MASTOIDECTOMY

To the Editor:—In several articles on skin grafting radical mastoid cavities in recent issues of the *Archives of Otolaryngology*, mention is made of the "Mosher paraffin basket." If there is an article on the technic of this procedure, I should like to obtain it and would be pleased to hear from you in this regard.

NORMAN C. COOK, M.D., Victoria, B. C.

ANSWER.—The paraffin basket mold for applying a skin graft to the radical mastoid cavity was described in the *Transactions of the American Otological Society* in 1925. The method of making the paraffin gauze basket and the present method of using it are as follows:

A strip of ordinary surgical gauze 6 inches wide and 12 inches long is folded on its long axis toward the center twice, making a four ply tape an inch and a half wide. The gauze tape is dipped into melted household paraffin or parowax. The coating should be thick enough to obliterate the meshes of the gauze. The impregnated tape is rolled up and placed in a sterile container. Ten or a dozen such pieces of tape will last the usual operator a considerable time. These rolls become solid when the paraffin cools. It is generally easy to unwind the roll when it is wanted for use. If it does not unwind readily, immersion in warm sterile water will start it.

Suppose that the radical cavity is finished and that the operator is ready to cut his graft. The cavity is cleaned and plugged with gauze soaked with epinephrine. This is left in while the paraffin basket is being made. There is a bit of a trick in making the cone. A strip of tape is cut 6 inches long. This is made to loop over the right index finger of the surgeon tent fashion, the ends of the tape diverging and making a V.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 29-July 1. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 2. Sec., Dr. W. W. Council, Juneau.  
ARKANSAS: *Medical (Regular)*. Little Rock, May 11-12. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Los Angeles, Feb. 8-11. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Basic Science*. New Haven, Feb. 13. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical (Homeopathic)*. Derby, Feb. 13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven. *Medical (Regular)*. Hartford, March 9-10. *Endorsement*. Hartford, March 23. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

IDAHO: Boise, April 6. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

ILLINOIS: Chicago, Jan. 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration, Dr. William R. Davidson, 301 State House.

KENTUCKY: Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MAINE: Portland, March 9-10. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Medical (Regular)*. Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic)*. Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEVADA: *Reciprocity*. Carson City, Feb. 1. Sec., Dr. John E. Worden, Carson City.

NEW HAMPSHIRE: Concord, March 11-12. Address, Board of Registration in Medicine, State House, Concord.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 25-28. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

OKLAHOMA: Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Basic Science*. Portland, March 20. Sec., Mr. Charles D. Byrne, University of Oregon, Eugene.

PUERTO RICO: San Juan, March 2. Sec., Dr. O. Costa Mandry, Box 536, San Juan.

VERMONT: Burlington, Feb. 10-12. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WEST VIRGINIA: Charleston, March 1. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Basic Science*. Madison, April 3. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, Feb. 1. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, January 16, page 230.

### Ohio June Report

Dr. H. M. Platter, secretary, Ohio State Medical Board, reports the oral, written and practical examination held in Columbus, June 16-19, 1936. The examination covered 10 subjects and included 80 questions. An average of 75 per cent was required to pass. Two hundred and eighty-three candidates were examined, 281 of whom passed and 2 failed. Fifty-eight physicians were licensed by reciprocity and 4 physicians were licensed by endorsement. The following schools were represented:

requirements is suggested. Restriction of fluids does not appear necessary, but elimination of table salt seems desirable. As for drugs that might have an effect in lowering the blood pressure, one hesitates to suggest sedatives in the absence of knowledge as to the patient's nervous state, or such preparations as nitrites or potassium iodide.

#### PREGNANCY AND HYPERTHYROIDISM

*To the Editor:*—Kindly suggest the management of a primipara, aged 25, six months pregnant, who has asymptomatic signs of hyperthyroidism; i. e., an enlarged goiter, tachycardia (a rate of 120), increased blood pressure (160 systolic, 70 diastolic), tremor, underweight, normal urine and a negative blood Wassermann reaction. Administration of aqueous solution of iodine produced no change. What treatment should be given during pregnancy? What anesthetic and/or analgesic should be chosen during labor? Is chloroform harmful here? What is the postpuerperal treatment for the hyperthyroid condition, medical if possible? Is a basal metabolism test absolutely necessary in view of the conditions found. Please omit name.

M.D., New York.

*ANSWER:*—Before an attempt is made to offer suggestions for the management of this particular case, it might be well to refer to some data that appeared in an article published in 1931: Twenty-nine cases of exophthalmic goiter, and twelve cases of adenomatous goiter with hyperthyroidism associated with pregnancy were reported; these cases had been observed during the period beginning in January 1923 and ending in January 1930. The symptoms in five (17 per cent) of the cases of exophthalmic goiter and in six (50 per cent) of the cases of adenomatous goiter with hyperthyroidism were aggravated during pregnancy prior to the inception of treatment. In twenty-two of the twenty-nine cases of exophthalmic goiter, partial thyroidectomy was performed during pregnancy. In the remaining seven cases of exophthalmic goiter the patients were carried through pregnancy on aqueous solution of iodine. In those cases in which thyroidectomy was performed, aqueous solution of iodine was administered for some time prior to thyroidectomy, but iodine did not sufficiently control the symptoms to warrant deferring operation until after labor. In nine of the twelve cases of adenomatous goiter with hyperthyroidism, thyroidectomy was performed during pregnancy. There were no deaths from thyroidectomy in the whole series, and all the patients reported relief or improvement of symptoms. Miscarriages were not reported in either group.

In conclusion, the authors made the following summary: "Evidence indicates that hyperthyroidism resulting from adenomatous goiter is not satisfactorily controlled by iodine and that it is safer to remove the adenomatous tissue if this condition is present. The use of aqueous solution of iodine in doses of 10 drops three times a day, in cases of exophthalmic goiter, should be followed by distinct improvement and a definitely lowered basal metabolic rate within two weeks. In the occasional case of exophthalmic goiter, within two weeks after the use of iodine, a remission may follow which is complete or nearly complete, with the basal metabolic rate approximating normal or within normal limits. In certain cases of such rapid and marked remission of the disease, the patient may be carried successfully through pregnancy by the administration of iodine, without resort to thyroidectomy. Patients must be observed carefully, however, and determinations of the basal metabolic rate must be made occasionally, as recrudescence of the disease often occurs in spite of the continued use of iodine. In the medical treatment of exophthalmic goiter in which there is marked response to iodine, the attending physician may acquire a false sense of security, which results in operation being deferred to a less favorable period in pregnancy or to a time when iodine may fail to give as complete protection against postoperative reaction. Except in certain cases in the later months of pregnancy, partial thyroidectomy should be performed without delay if the exophthalmic goiter does not show complete or nearly complete remission within two weeks after the institution of treatment with iodine; delay may be followed by irreparable injury to vital organs. There may be exceptions to this rule in cases in which complicating conditions other than normal pregnancy exist. In cases of exophthalmic goiter and of adenomatous goiter with hyperthyroidism in which operation is or is not performed, aside from the judicious use of iodine the treatment is the same as that usually given to women during pregnancy and confinement. When the strength of the patient is diminished or the heart is injured as a result of the severity of the hyperthyroidism, it may be necessary to shorten labor by forceps or version or, rarely, by cesarean section."

The data presented in the article referred to and the authors' summary will serve as a guide in the management of the case under consideration. Determinations of the basal metabolic rate

should be made from time to time as an aid in diagnosis and in determining the advisability of thyroidectomy. It should be remembered, however, that even in the absence of hyperthyroidism an increase in the basal metabolic rate begins about the fourth month of pregnancy and rapidly increases, particularly during the last three months. At the end of pregnancy the rate may be from 20 to 25 per cent above the Du-Bois standard if calculated in the ordinary manner without allowing for the development of the fetus. Therefore, a basal metabolic rate of +25 or even +30 is not necessarily an indication of hyperthyroidism in the latter months of pregnancy.

In cases in which hyperthyroidism is associated with pregnancy, pentobarbital sodium, 3 grains (0.2 Gm.) orally, may be administered as an analgesic in the early part of the first stage of labor, but it is usually inadvisable to give more than a total of 6 grains (0.4 Gm.) during this period of labor. Morphine,  $\frac{1}{6}$  grain (0.01 Gm.), may be given hypodermically if it is not given within four hours of actual labor. Chloroform should not be used in this type of case during labor; nitrous oxide and oxygen is the anesthetic of choice.

#### TREATMENT OF GONORRHEA

*To the Editor:*—I have a patient who came to me with the usual symptoms of gonorrheal infection although the story was that the condition was due to a "strain from horseback riding." The smear taken at the first visit was reported "positive" for specific organisms and treatment was immediately started with the filtrate of Corbus-Ferry. Subsequent treatment consisted of daily irrigations with neosilvol solution and weekly injections of the filtrate. Twenty filtrate injections were given in all, the dose varying from 0.05 to 0.1 cc. intradermally. Smears taken at these weekly intervals were negative for gonococci until the eighth week, when it came back positive. Treatments were continued as before with prostate massages begun at this time, a few drops of a milky secretion being obtained at each of these visits. For the next eight weeks the smears remained negative but the eighth was again positive. Treatment continued as before, but after the twentieth filtrate injection these injections were discontinued. The prostatic smears came back negative but always had "a few leukocytes," and the morning drop also continued. After eleven more weeks the patient contracted a prostatitis, caused perhaps by sitting on cold and damp ground. The gland became hard, swollen and tender. Hot sitz baths relieved the pain and pressure in the perineum but the discharge started up profusely and was again positive for gonococci. The patient has had twenty-six weeks of treatment, twenty of which consisted of filtrate injections with the neosilvol washes and the use of methenamine and copaiba-methylene blue combinations alternating orally. On the twentieth week he complained of splitting of the stream and frequency. Feeling that there must be a stricture, I dilated the urethra on two successive weeks with No. 11 and 13 English sounds. Adequate sterilizing precautions were taken and this condition has improved. Treatment has certainly been adequate, perhaps too adequate, for this to be cleared up by now and I should like to know what measures I might take to cure the condition. He wishes to get married as soon as possible but not before he is perfectly "healthy," and I want to be able to reassure him that he has recovered. He has followed treatment very well and has avoided all sexual exercise and other deleterious practices and I feel that something is amiss although I cannot put my finger on it. I feel that the filtrate in this instance has proved bacteriostatic but not bacteriocidal and that it merely held up the discharge as long as he was receiving the injections. I am now giving irrigations with neosilvol and also using four irrigations daily of zinc sulfate 10 grains (0.65 Gm.), diluted solution of lead subacetate 4 ounces (120 cc.) and water to make 8 ounces (235 cc.) following urination in an attempt to dry up this discharge. Please omit name.

M.D., Massachusetts.

*ANSWER:*—This patient most probably has his gonorrhea from a persistent focus in the prostate and vesicles and from overzealous therapy. If the patient has two cloudy urines he should be treated twice a week with gentle massage of the vesicles and prostate. The force of the massage may be gradually increased but should never produce real pain, only the discomfort usually associated with this procedure. After each massage a 5 per cent solution of mild protein silver should be instilled through a catheter into the posterior urethra. The anterior urethra can be medicated as the catheter is being withdrawn. Should the cloudy urines contain considerable flakes of exudate, it is usually beneficial to substitute a through and through irrigation of 1:5,000 potassium permanganate solution for one of the instillations. The irrigator containing the permanganate solution should not be more than 3 or 4 feet above the patient. This procedure should produce no pain, otherwise more harm than good will result. After the prostatic and vesicular secretions improve and the urine gets fairly clear and contains only shreds, the treatment is again altered. In place of two massages the patient is treated with a sound at one visit and is massaged the next. Following these procedures the urethra should receive a through and through injection of mild or strong protein silver in the strengths mentioned. The dilation should be begun at 23 or 25 F., depending on the size of the meatus. The size

**Handbuch der biologischen Arbeitsmethoden.** Herausgegeben von Geh. Med.-Rat Prof. Dr. Emil Abderhalden, Direktor des Physiologischen Institutes der Universität Halle a. d. Saale. Abt. V, Methoden zum Studium der Funktionen der einzelnen Organe des tierischen Organismus, Teil 3B, Heft 6. Lieferung 451. Auxine. Von A. N. J. Heyn. Darstellung des Melanophorenhormons. Von F. Dietel. Darstellung und Wirkungsprüfung des Fettstoffwechselhormons und des Kohlehydratstoffwechselhormons des Hypophysenvorderlappens. Von Karl Julius Anselmino und Friedrich Hoffmann. Hypophysektomie. Von A. Geesink. Darstellung und Eigenschaften des kristallisierten Insulins. Von Oskar Wintersteiner und Hans Jensen. Untersuchungen der hormonalen Funktion der Thymus. Von Leon Asher. Paper. Price, 6 marks. Pp. 823-936, with illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1936.

This volume contains reviews on the isolation and properties of the plant and animal hormones. The comprehensive treatment of the growth hormone "Auxine" by A. N. J. Heyn gives a discussion of the various practical preparations of the hormone and gives an excellent proof of its chemical structure. Biologic tests are described in detail and are accompanied by helpful illustrations of apparatus used in assaying the preparations.

The literature regarding the preparation of the melanophore hormone from the posterior lobe of the pituitary gland is briefly reviewed by F. Dietel. The research on this interesting substance is still in its early stages. Unfortunately, the author has not endeavored to bring the bibliography down to date.

K. J. Anselmino and F. Hoffmann describe the preparation and tests for the ketogenic and blood sugar raising hormone of the anterior lobe of the pituitary gland. It is a short treatise but covers the literature to date.

A. Geesink describes the technic of hypophysectomy. The clear, concise exposition should enable any biologic worker to follow his method. The necessary instruments and their uses are mentioned, and detailed illustrations of the various phases of the operation are given. The paper includes a valuable bibliography of the surgical anatomy of the pituitary gland.

O. Wintersteiner and H. Jensen review the preparation and properties of crystalline insulin. In view of the fact that the practical preparation of insulin is mostly a commercial trade secret, the authors describe only the classic works of Abel and of Harington and Scott. The physical and chemical properties of insulin are briefly mentioned. It is regretted that the bibliography is reviewed only to 1933, making this otherwise valuable presentation somewhat obsolete.

A short review of the hormonal function of the thymus is contributed by Leon Asher. Nutrition of the animals, extirpation of the thymus, preparation, and tests for identification of the active principle, which he calls "thymocrescin," are briefly discussed. Comparisons with extracts of other organs are given. References to the original literature are scanty.

It would be desirable for the publisher in the future to ask the authors to complete the bibliographies in a short supplement, should the presentations have been written long before the printing was finished.

**The Practice of Medicine.** By Jonathan Campbell Meakins, M.D., LL.D., Professor of Medicine and Director of the Department of Medicine, McGill University, Montreal. Cloth. Price, \$10. Pp. 1,343, with 505 illustrations. St. Louis: C. V. Mosby Company, 1936.

Perhaps a dozen different textbooks of the practice of medicine now appeal for the favor of students and practitioners. Dr. Meakins does not attempt here a treatise for specialists or an encyclopedia but rather a book of usefulness to students and practitioners as a reference. Unlike many other authors of textbooks of the practice of medicine he has relied largely on illustration to aid in advancement of knowledge and the book is supplemented by more than 500 halftones and other illustrations, including many plates in colors. He has been aided in his development of the book by his colleagues on the faculty of McGill University.

In his approach to the subject he begins with the diseases of the nose and throat and then takes up system by system, concluding with the infections, allergy, environment and drugs. Each of the chapters in the book is supplemented by a brief bibliography and the author refers frequently in the course of his writing to his source of information. There is little or no ornamentation of style and the volume is but slightly personal in its approach to any of the subjects that are discussed. It seems rather to be a straightforward, concentrated statement of the available established knowledge, planned to give funda-

mental facts to the user as quickly as possible. An occasional footnote in small type is found devoted to a personal reference by the author to individual cases that he has seen. The striking feature of this textbook is unquestionably the illustrative material.

**Entomological Studies: Studies on Insects of Medical Importance in South Africa—Part III.** By Botha De Meillon, D.Sc., F.R.E.S. From the Malaria Research Station of the South African Institute for Medical Research, at Eshowe, Zululand. Publications of the South African Institute for Medical Research—No. XXXVIII. (Vol. VII). Paper. Pp. 125-215, with 32 illustrations. Johannesburg: The Institute, 1936.

The first three parts consist of short articles on *Anopheles* mosquitoes. Studies on the egg, larval, pupal and imaginal stages of *Anopheles listeri* place it in the turkhudi group. Eggs of *A. coustani* and *A. coustani* var. *tenebrosus* are figured and described. Actual distribution of *A. gambiae* and *A. funestus* in Natal does not coincide with the distribution that would be determined by climatic factors. Breeding of *A. gambiae* is restricted by dense growths of vegetation, usually cane. It is thought, therefore, that the droughts of 1928, 1930 and 1931 paved the way for the serious epidemic of malaria in 1931-1932 by reducing the amount of such vegetation. Physical features such as mountains do not favor the breeding of *A. funestus*, for in such localities the streams are being continually flushed. Part 4 is a list of South African *Ceratopogonidae* previously reported, and part 5 deals with new and unrecorded species of these insects. Twenty-four new species belonging to twelve genera are described and illustrated, and there is one new record of a previously described species. In part 6 three new species of *Simulium* are described.

**A Laboratory Manual of Qualitative Chemical Analysis for Students of Pharmacy.** By Theodore J. Bradley, Ph.D., A.M., B.S., Dean and Professor of Chemistry in the Massachusetts College of Pharmacy. Fifth edition. Cloth. Price, \$2.25. Pp. 170. Philadelphia: Lea & Febiger, 1936.

The purpose of this manual is to acquaint the student with general laboratory methods of qualitative analysis and to aid him to make such tests for identity and purity as come within the purview of a pharmacist. The course, for which the book is a guide, is arranged to occupy from four to five hours a week during one school year. The metals are classified in the customary seven groups for identification. No new methods are described in the procedure. Each group is treated as a separate chapter, at the end of which is a cumulative chart for the identification of all the elements in the preceding groups. The acids are divided into three groups for identification: (a) acids precipitated by silver nitrate, (b) acids precipitated by barium chloride and (c) acids not precipitated by either of the foregoing methods. Directions are also given for the analysis of metals and acids in the same solution. For each metal and acid identified in the procedures are given its important compounds. Short chapters are included on topics such as the qualitative analysis of a solid, qualitative examination of official inorganic chemicals, destruction of organic matter, qualitative tests of the United States Pharmacopeia, and reagents and test solutions. As a laboratory guide the manual covers the essentials of inorganic qualitative analysis for those who wish a fairly superficial course but is in no sense a reference book. Conspicuously absent is the consideration of the theoretical aspects of qualitative analysis. Throughout the book the author refers to the anions and cations as acids and metals.

**A Text Book of Pharmacognosy.** By Heber W. Youngken, A.M., Ph.D., Ph.D., Professor of Pharmacognosy and Materia Medica in the Massachusetts College of Pharmacy, Boston. Fourth edition. Cloth. Price, \$7. Pp. 324, with 469 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1936.

This textbook, primarily intended for students of pharmacy, has undergone a thorough revision and contains much new material and illustrations. The book is divided into two parts. Part I deals with morphologic considerations of drugs and includes the sections dealing with fundamental considerations, such as collection, curing, valuation, sampling and preservation. Part II contains a taxonomic consideration of drugs and additional information concerning their description, history and constituents. The chapter on animal drugs has been expanded to include new monographs on endocrine gland

strated to arise from local causes only, it is important that it be controlled. It is apparent that the Ace bandages are inadequate for this purpose. It is well to try next good grade elastic stockings, for which measurements are taken when the extremities are free of edema. If these do not control the swelling, it is advisable to use a pure rubber bandage which is 3 inches wide and 15 feet long. These bandages can be secured in three weights, and it is probable that the lightest one would be satisfactory. Discussion of the differential diagnosis of swelling of the extremities, and instructions for the use of bandages is available (*Ann. Int. Med.* 9:516 [Nov.] 1935).

#### CARE OF DISCHARGE IN OTITIS MEDIA

*To the Editor:*—Some nose and throat men say that a discharging ear should not be irrigated because it might produce a mastoiditis, while other nose and throat men say that the canal should be irrigated or washed out. What is the right or proper thing to do? Is it proper to put anything into the discharging ear, or not, and if so what is the best remedy? Would the instillation of five drops of alcohol three times a day be indicated and would it be as good as almost anything else one might instill into the ear? I am a general practitioner and I was taught to use heat in all cases of mastoiditis, especially moist heat, such as hot epsom salt compresses. I was instructed never to irrigate a discharging ear but to leave it alone and let it discharge. Please omit name.

M.D., New Jersey.

**ANSWER.**—In the presence of an acute otitis media the discharge in the external auditory canal may be treated either by the dry method—mopping it up with absorbent cotton—or by the wet method—flushing the canal with some mild antiseptic fluid such as a saturated boric acid solution.

In acute suppurative otitis media the pathologic condition is such that it is not likely that any of the irrigating solution will enter the middle ear; hence the fallacy of using highly recommended expensive antiseptics. The irrigation is merely a mechanical method for obtaining the result desired. The situation is entirely different when one deals with a chronic suppurative otitis. In chronic suppurative otitis, cholesteatoma is frequently present. Watery solutions in the external auditory canal may enter the middle ear and cause the cholesteatoma to swell, and occasionally under such circumstances serious if not fatal complications may result. Hence aqueous solutions are forbidden according to the best teachings.

If the discharge in the presence of chronic otitis media is such that irrigations are deemed necessary, one should use alcohol solutions. Alcohol is a dehydrating agent and will not cause the cholesteatoma to swell, provided the concentrations used vary from 60 per cent upward. It is perfectly proper, however, to use alcohol drops in the presence of chronic suppurative otitis media, and they may also be used in the last stages of acute otitic suppuration. It seems clear that the statement that a discharging ear should never be irrigated is not altogether true. Within the limitation given, it is perfectly proper to wash out the external auditory canal.

#### REGROWTH OF PROSTATE AFTER ENUCLEATION

*To the Editor:*—A man, aged 70, has occasional painless hematuria. He says that he had an enucleation of the prostate fourteen years ago. The surgeon is now dead but his son, who is carrying on the practice, reports two other cases that his father had treated with enucleation, in men younger than the average prostatic patient, who have returned to him with benign hypertrophies after ten and eighteen years respectively. On physical examination of this one patient I find a smooth, hypertrophied left lobe and a smaller and somewhat roughened right lobe, with slightly increased density. A 15 ounce residual urine was found, a soft rubber catheter having been introduced without difficulty. I have attended this patient for the past eight months, during which time he has had a bronchopneumonia with apparent complete recovery, followed by hemorrhage from a peptic ulcer. The latter condition has progressed satisfactorily to date. Can you give me any information regarding regrowth of the prostate? Do you advise enucleation at this time? Your comments on this subject would be greatly appreciated. Please omit name.

M.D., New Hampshire.

**ANSWER.**—Regrowth of the prostate gland following its surgical removal is not at all uncommon. It is usually impossible to remove all the prostatic tissue at operation, and hyperplasia of the remaining tissue occurs to a varying degree in a large number of cases. As a rule the regrowth is slight and causes no symptoms, but evidence of postoperative urinary obstruction is noted in possibly 5 per cent of cases. Usually such obstruction does not take place until ten or fifteen years following enucleation, and it occurs more frequently in patients who were under 60 years of age at the time of operation.

Removal of the prostatic obstruction is undoubtedly indicated. With perfection of the methods of transurethral resection there is no reason why another enucleation should be performed in this patient. A transurethral resection, if done by a man who has had considerable experience in this field, should be accompanied by comparatively little risk to the patient, and the function of his bladder should be restored to normal. Curiously enough, transurethral resection has been inadequately developed in some sections of the country. However, the excellent results which usually follow this operation make it the method of choice.

Before anything is done, an examination should be made to determine the cause of the patient's painless hematuria. Although hematuria is often of prostatic origin, the possibility of a neoplasm or possibly a nonopaque calculus in the bladder cannot be excluded without cystoscopy. If there are clinical data which would suggest that the hematuria might be of renal origin, an excretory urogram or, better, a retrograde pyelogram will usually exclude this possibility.

#### CHRONIC PROSTATITIS

*To the Editor:*—A white man, aged 24, became infected with gonorrhea seven years ago. He received treatment at that time, consisting of "pills" orally and self hand injections once daily for four months until the discharge ceased. For the next three months he received prostatic massage. No sounds were used. The patient was told that he was cured. Three years later he married. About one year after marriage, or after four years of being symptom free, he had a recurrence of the white penile discharge. He went to another physician and was treated for one month by means of intra-urethral self hand injections. At the end of one month the discharge stopped and his physician said that the discharge "would dry up." A smear at this time showed few pus cells and no organisms. The patient was symptom free for the next two years, when he again developed a urethral discharge. He went to another physician, whose treatment was the same as that described but in addition he passed sounds about three times. During this treatment a left cervical abscess developed. While the patient went to the hospital for treatment of this condition the urethral discharge persisted for the next two months. After leaving the hospital he resumed his gonorrheal treatment, which lasted several months until October 1935, when the discharge from the urethra ceased. A smear at that time showed nothing. The patient was then symptom free until February 1936, when he consulted me. At that time a urethral discharge developed. A smear showed only a few pus cells and no organisms. During my treatment, which consisted of prostatic massage and the passage of sounds with instillations of 1 cc. of 0.5 per cent silver nitrate into the posterior urethra through an Ultzman tube, the discharge has stopped. The discharge is present only after prostatic massage. The prostate is normal in size and is not tender. He has refrained from the use of alcohol but continues his sexual relationship. I would greatly appreciate it if you will criticize this case from beginning to end and offer your opinion as to any further procedure to be taken. The patient's wife has not developed any symptoms referable to gonorrhea. Please omit name if printed.

M.D., New York.

**ANSWER.**—A recurring urethral discharge of this type usually has its origin in a chronic infection of the prostate gland. The possibility of recent reinfection, of course, is not excluded. Bacterial study of a discharge persisting many years after an initial gonorrheal infection seldom reveals the presence of *Neisseria gonorrhoeae*. In order to make certain, however, it would be well to take cultures of the discharge for *Neisseria gonorrhoeae*, since recent technical advance in its culture has made this method remarkably accurate.

Chronic, recurring infection of the prostate gland may be difficult to eradicate. A thorough and repeated study should be made of the prostatic secretion, note being made of the cellular contents as well as gram stains and cultures. Although only a few pus cells may be found on preliminary massage, subsequent massage may disclose evidence of considerable prostatic infection. A course of vigorous prostatic massage over a period of two or three months would then be indicated. Dilating the urethra with sounds and deep urethral injections may also be employed. Although chronic prostatic infection is probably favored by a previous gonorrheal infection, it occurs fully as often without such involvement. Chronic prostatitis may be secondary to infection elsewhere, as in the teeth and tonsils. It would be advisable to search for such foci and remove them if found.

If the discharge persists in spite of the treatment suggested, it would be advisable to make a cysto-urethroscopic examination in order to exclude first the possibility of infection in the upper urinary tract and also to localize the condition of the prostatic urethra. If dilated ducts exuding purulent secretion are seen in the prostatic urethra, this would indicate active prostatic infection and the possibility of a duct abscess. If evidence of a localized abscess is found, transurethral incision of the ducts would be indicated. If no surgical condition is found and

A Dissertation on the Sensible and Irritable Parts of Animals. By Albrecht von Haller. [London, J. Nourse, 1755]. Introduction by Owsei Temkin. Boards. Price, \$1. Pp. 49, with one illustration. Baltimore: Johns Hopkins Press, 1936.

Following a brief introduction to the topic by Owsei Temkin in which is told a little of the life of the famous von Haller, this book provides a reprint of one of von Haller's most famous essays. It indicates how great a part he played in the development of experimental physiology.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Malpractice: Roentgen Burn.**—The defendant, a physician, utilized roentgen therapy in treating the plaintiff for a condition of the skin described as "eczema or some kindred ailment." Alleging that by reason of the defendant's negligence she sustained burns on her scalp, face, arm and breast, the plaintiff brought suit. The trial court gave judgment for the plaintiff, which the court of civil appeals, Texas, affirmed after requiring a remittitur (62 S. W. (2d) 600; abstr. *THE JOURNAL*, March 24, 1934, p. 960). The defendant then appealed to the Supreme Court of Texas.

It was undisputed, said the Supreme Court, that, at the time the plaintiff called on the defendant for medical treatment, she was suffering from eczema or some kindred ailment. The plaintiff's evidence tended to show that as the result of the roentgen treatment she sustained roentgen burns, that she had lost her hair, which at the time of the trial had been partially restored, that the skin on her face, arms and breast had "peeled off," leaving the surface sensitive and irritable, and that she had suffered physical and mental pain as a consequence of her injuries. The defendant, on the other hand, offered evidence tending to show that the plaintiff's condition at the time of the trial was due to "eczema or some disease of that type." On appeal, the defendant contended that the trial court had erred in refusing to present the following special issues to the jury:

Is Mrs. Rachel La Grone's condition the result of a disease known as eczema?

Is Mrs. Rachel La Grone's condition the result of some disease other than the application of the x-ray?

It is obvious, said the Supreme Court, that these requested charges were not correct, and, if answered in the affirmative, would not have constituted a complete defense to the plaintiff's case. Even if the plaintiff's condition at the time of the trial was due to eczema, nevertheless she could have suffered various injuries as a result of the burns, as claimed by her, and her condition could have been materially different at the time of the trial from what it was, as shown by her testimony, immediately after the treatment. The question really resolved itself into an inquiry as to what extent, if any, the eczema contributed to the injuries suffered by the plaintiff, and this question was not raised in the special issues which the defendant requested be given to the jury. The Supreme Court could find no reversible error in the record and affirmed the judgment of the court of civil appeals.—*Kenny v. La Grone (Texas)*, 93 S. W. (2d) 397.

**Malpractice: Criteria of Standard of Skill and Care Required of Physicians.**—The Columbia Health Foundation sold "health and medical services and hospitalization" for a stipulated sum per month. The Angelus Hospital Association, also referred to in the record as R. B. Jenkins, Inc., operated a hospital wherein it "took care of the customers" of the Health Foundation for a stipulated sum. Dr. R. B. Jenkins was the president of the corporation hospital, the principal owner of its stock, and its general surgeon. The plaintiff was apparently a "customer" of the Health Foundation and his wife was admitted to the hospital for her confinement. The baby developed impetigo and subsequently died, whereupon the plaintiff sued the Health Foundation, the hospital corporation, and certain physicians employed by the hospital, alleging negli-

gence in permitting the baby to contract impetigo, in treating it thereafter, and in discharging the plaintiff's wife and her baby at a time when the baby was still suffering from "an acute attack of impetigo." The plaintiff obtained judgment against all the defendants, who, with the exception of those connected with the Health Foundation, appealed to the district court of appeal, second district, division 1, California.

The principal issue raised on appeal had relation to the form in which a certain hypothetical question was put to an expert witness for the plaintiff. The vice attributed to the question was that it sought from the witness an opinion as to whether the particular physician whose alleged negligence was at issue had exercised that degree of skill, care and learning ordinarily possessed and exercised by physicians and surgeons practicing in Los Angeles in the treatment of similar conditions. Technically, said the court, the appellants' objection was correct. When a hypothetical question is put to an expert witness the evidence sought is not what the witness personally thinks of what was or was not done, not whether he would do or omit to do the particular act or omission charged as negligence, not whether the actual physician in the case was negligent in the commission or omission charged, but whether, in the opinion of the witness, a physician of ordinary attainments practicing in the same locality and using ordinary skill and care would have done or failed to do the thing charged. An expert witness, continued the court, gives his opinion with respect to whether the doing or not doing of a certain thing conforms to what a hypothetical physician, endowed with ordinary skill and learning and exercising ordinary care and prudence, practicing in the locality in question, would or would not do. Such an opinion, in legal supposition, is different from saying that the actual physician in a given case is skilled or unskilled, careless or careful. The expert's opinion sets up for the use of the jury or the court a hypothetical physician, by which the jury or court may test the skill of and the care used by the physician actually involved. While the hypothetical question propounded in this case did seek to elicit from the expert witness an opinion as to whether or not the particular physician exercised the required degree of care, the court was of the opinion that the objectionable form of the question did not constitute prejudicial error because, in answering the question, the witness stated: "The treatment differs from the usual treatment of these conditions." This answer, the court said, gave the jury exactly the information that the question should have called for if it had been framed correctly. While the question was incorrectly framed, the answer itself did not constitute an invasion of the province of the jury.

The appellants contended also that the plaintiff's contract called only for obstetric services to the plaintiff's wife and did not require any care for the baby. Such a distinction, the court said, is too strained to be substantial. When an obstetrician undertakes to deliver a woman of a baby, he may not devote his entire attention at the time and during the hospital confinement to the mother alone. It should be said, pointed out the court, in justice to the physicians involved in this case that they undoubtedly felt under obligation to care for the baby, since they did proceed to look after it.

The record in this case, concluded the court, substantially supported the jury's verdict for the plaintiff. The judgment of the trial court was therefore affirmed.—*Criss v. Angelus Hospital Assn. of Los Angeles (Calif.)*, 56 P. (2d) 1274.

- American Orthopsychiatric Association, New York, Feb. 18-20. Dr. George S. Stevenson, 50 West 50th St., New York, Secretary.
- Annual Congress on Medical Education, Medical Licensure and Hospital Administration, Chicago, Feb. 15-16. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.
- Pacific Coast Surgical Association, Seattle, Wash., and Victoria, B. C., Feb. 24-27. Dr. H. Glenn Bell, University of California Hospital, San Francisco, Secretary.
- Southeastern Surgical Congress, Louisville, Ky., March 8-10. Dr. Benjamin T. Beasley, 478 Peachtree St. N.E., Atlanta, Ga., Secretary.
- Western Section, American Laryngological, Rhinological and Otolaryngological Society, San Diego, Calif., Jan. 30-31. Dr. David R. Hixson, 1145 Fourth Ave., San Diego, Calif., Chairman.

PAIN IN COSTOCHONDRAL JUNCTION AFTER  
A FALL

*To the Editor:*—A white man, aged 40, fell a distance of about 4 feet while carrying two heavy pails of gasoline, about eleven months ago; he landed hard on his heels and immediately fell down, although retaining consciousness. As a direct result of the fall, landing on his heels, and continuing his hold on the pails, he felt a sharp stabbing pain in the region of the sixth or seventh costochondral junction on the right side. He was strapped for several weeks but continued to have this recurrent pain, which appears to shoot upward along the right sternal margin, across to the precordium, and is aggravated by any movement of the right arm which involves abduction. Roentgenograms taken at the time of the injury and repeatedly since reveal no demonstrable injury. Shortly after the accident he "vomited" up several pieces of tissue that looked like liver and has had no more attacks of vomiting. At the present time there is still pain and "clicking" in this region on abduction of the right arm, and any attempt at work (ordinary labor and truck driving) causes rapidly increasing pain in the area and some vertigo. The patient has been told at several clinics that he is suffering from hypoglycemia, bronchitis and nerves. But how can one explain the present disability, the persistent soreness over the sixth costochondral junction, the recurring click in the region? My diagnosis is "chronic subluxation of the right sixth costochondral junction with traumatic neurosis." Kindly omit my name.

M.D., Michigan.

*ANSWER:*—If this is a compensation case, the patient's progress will be delayed.

If the location of the click can be accurately determined or demonstrated by the stethoscope, exploration is advisable. Rupture of the diaphragm may enter into the discussion. There may be a vertebral injury. Are there any other evidences of neurosis? Roentgenograms made from various angular projections or stereoscopically may be helpful. The arm should be adducted and abducted during successive exposures. The measures of treatment that may be considered are physical therapy, a compression band, a brace, living suture with fascia lata and a fusion operation.

## PAPILLOMA OF BREAST

*To the Editor:*—A woman, aged 28, about 5 feet 8 inches (173 cm.) in height, weight 220 pounds (98 Kg.), began to menstruate at the age of 13; the menses were regular and normal. At 14 she had an appendectomy, at 19 a tonsillectomy and at 21 a double salpingectomy because of pus in the tubes, apparently due to a mixed infection of gonococcus and staphylococcus. About three years ago, when 25 years of age, she had a hysterectomy because of severe dysmenorrhea and menorrhagia. A few months later there started a bloody, serous discharge from the right nipple, which lasted off and on for a few months. No tumor mass was found and the condition cleared up and has not bothered her since until last week. Now it has begun again. No tumor mass is found at the present time. She has a tired feeling in her arms and shoulders and a feeling of numbness of the skin over both breasts and up through to the clavicle. Her breasts are large and pendulous from excessive fat. She carries them well supported, but not much compressed, by a supporting type of brassiere. What treatment would you advise? Is there any great probability of this becoming carcinomatous or malignant? Please omit name and address.

M.D., Minnesota.

*ANSWER:*—The trouble is probably an intercanicular papilloma of the breast. This is ordinarily a benign growth, commonly so small that it is not palpable. Surgical intervention is preferable to palliation, because there is a rather high incidence of malignancy in such cases.

It is true that there is a close interrelationship between diseases of the ovary and disturbances of the mammary glands. But vicarious menstruation, such as might be thought of in this connection, probably does not occur; at least it is not accepted as a clinical entity by leading gynecologists. Other disturbances of the breasts ascribable to genital stimulation would scarcely be sufficient to produce a bloody discharge from the nipples.

## RAREFYING CONDITIONS OF BONE

*To the Editor:*—An atrophic condition of the bones of the elbow is present. I am concerned chiefly with the possible causes that may be responsible. I am especially interested in what is known as Leriche's disease of bone. The irregularity of the condyle is due to perforation of the osteoporotic areas through the cortex and not to an old fracture. Any further information and references to Leriche's disease of bone will be appreciated. Please omit name.

M.D., New York.

*ANSWER:*—Leriche's or Sudeck's disease is discussed by King in his book "Rarefying Conditions of Bone," pages 293-307. It may be caused by trauma to nerves or to the vascular system, by disuse or by infection. It also may be reflex ("trophic").

"Leriche has very clearly stated a view which is a modification of the trophic theory. He showed that resorption of bone was often associated with an increased blood supply, and he maintained that bone resorption always occurred as the direct

result of augmentation of the blood flow. He also states that diminution of the blood supply results in sclerosis.

"This increase in the blood supply he regards as being the result of a vasomotor reflex—'des reflexes d'axone traumatique.' Although all of Leriche's statements cannot be accepted in their entirety, his contribution is one of the most valuable of recent times."

Further information on this subject may be obtained from Leriche's original articles, which are as follows:

1. Leriche, R.: Sur quelques maladies osseuses et articulaires d'origine vasomotrice et sur leur traitement, *Bull. et mém. Soc. nat. de chir.* 53:1022 (July 16) 1927.
2. Leriche, R.: Osteoporose bi-épiphysaire du genou, prise pour une tuberculose: Guérison par injections d'extrait ovarien; Résultat datant de vingt-sept mois, *ibid.* 58:434 (March 12) 1932.
3. Leriche, R., and Policard, A.: Les Problèmes de la physiologie normale et pathologique de l'os, Paris, Masson et Cie, 1926.

## TREATMENT OF SYPHILIS

*To the Editor:*—A man, aged 52, whose weight was about 190 pounds (86 Kg.), complained of severe tinnitus that had existed more than twenty-five years. I found positive Argyll Robertson pupils and the blood Wassermann reaction 4 plus. It is remarkable that nothing of that kind had been found in former examinations by known and experienced physicians. The patient didn't show other signs. The knee jerks were normal. There was no Rosenberg sign. After a course of ten intramuscular injections of iodobismutol twice a week, he felt much improved. May I after a pause of four weeks continue with a combined bismuth-nearsphenamine course—the latter first in doses of 0.15 Gm? Tryp-arsamide is contraindicated because an ophthalmologist has stated that especially one eye shows a considerable contraction of the visual field and enlargement of the blind spot. If possible, spinal puncture should be omitted. May I have your suggestions? Please omit name and address.

M.D., New York.

*ANSWER:*—It would be advisable to continue treatment with bismuth or mercury compounds and iodides. Because of the potential danger of optic atrophy in this case, the arsphenamines should be withheld, at least until several courses of the metals have been given. It may then be used with great care, provided the defects in the visual fields become stationary or improve. A mild treatment over a long period will be found to be more advantageous than a shorter intensive treatment. The possibility of the future use of fever should be kept in mind.

## TREATMENT OF WRIST DROP

*To the Editor:*—Please outline the correct treatment for wrist drop in a middle-aged woman. There is complete loss of the power of extension. The etiology seems quite certainly to be alcoholic neuritis. What is the prognosis? Will the wearing of a splint and removal of alcohol be sufficient to bring about recovery? If published, please omit name and place.

M.D., Connecticut.

*ANSWER:*—Many patients with drop wrist due to alcoholic neuritis make a satisfactory recovery. The internal use of alcohol should be prohibited. A cock-up splint should be applied along the flexor surface of the forearm, to the ends of the fingers, with the wrist bent backward (extended) at an angle of 35 degrees. This splint should be removed twice daily for massage and muscle training.

In case the paralysis of the extensor muscles should prove to be permanent, a satisfactory functional result can be attained by transplanting the flexor carpi radialis into the extensor tendons of the thumb, and the flexor carpi ulnaris into the extensors of the fingers. Some operators also transplant the pronator radii teres into the extensor carpi radialis longus and brevis.

This form of operative treatment is highly successful in cases in which the musculospiral (radial) nerve has been cut or destroyed but is not often required in cases of alcoholic neuritis.

## TOXICITY OF SNAKE ROOT

*To the Editor:*—I have a patient who from time to time takes Canadian snake root, which he chews for the purpose of eliminating the odor of alcohol on his breath. I am anxious to know whether or not there is any possibility of toxicity arising from this habit. If you have any information, I would appreciate receiving a reference covering this question. Kindly omit name.

M.D., Massachusetts.

*ANSWER:*—Canada snake root, or wild ginger, is official in the National Formulary as *Asarum*. It contains aromatic oil and resin, and it is no more toxic than jamaica ginger. A brief description of the drug and its properties is to be found in "Pharmacotherapeutics," by Solomon Solis-Cohen and T. S. Githens, New York and London, D. Appleton & Co., 1928, page 821.

sensitiveness looked for in some cases of migraine. It seems probable that in some cases constipation is due to the irritation of the colon by certain foods, and in some the symptoms of cholecystitis, ulcer or appendicitis can be imitated with great fidelity. It does not seem logical to assume that most of the annoyances that follow the eating of particular foods are allergic in origin and due to protein. There must be druglike substances in certain foods which can upset the digestive tract in much the same way as a small dose of emetic or purgative. Whether or not one accepts the view that food sensitiveness is usually due to the protein in the food, the author cannot see why one should make strenuous efforts to purify the allergens used for skin testing. He believes that the best results should be expected with antigens obtained by the simplest treatment of the foods. It is neither logical nor necessary to keep a patient on a narrow elimination diet for weeks or months, as such diets are for diagnostic and not for therapeutic purposes. Sometimes positive skin tests can actually be a nuisance to both the patient and the physician as such blind and unswerving faith is put in them. The digestibility of a food may at times be much more important to a patient than is its content of vitamins or calcium or iron.

#### Antitoxin in Serum After Antidiphtheria Inoculations.

—In terms of antitoxin units per cubic centimeter of serum, Faragó observed that the average antitoxin serum content of blood, tested two years after immunizing inoculation with Ramon toxoid and toxoid precipitate, of individuals from four different districts of Hungary, was 0.68 for a group of forty-nine individuals, 0.257 for fifty, 0.562 for forty-seven and 0.567 for fifty-five. In the four groups subjected to tests the serum antitoxin content corresponded to the results of Schick reactions, although in one group the correspondence was not close. The level at which both Schick positive and negative reactions were obtained in three groups was 0.009 antitoxin unit per cubic centimeter of serum. Owing to probable technical errors it was impossible to define a level in the other group. Two years following immunization, immunity in three groups averaged, according to Schick reactions, 91.4 per cent, and according to antitoxin determination, 90.73 per cent. In one group the corresponding percentages were 86 and 76 per cent.

#### Treatment of Retinal Gliomas by Roentgen Radiation.

—Since a few small or massive doses of radiation had not given reasonable success in the treatment of retinal gliomas in the past, Martin and Reese employed a highly fractionated large total dose. To spare the eye from the undesirable and even serious effects of a large dose of radiation, they used small circular portals, accurately directed so as to confine the beam of roentgen radiation as much as possible to the region of the growth itself. The radiation was given as frequently and in as large doses as was compatible with the maintenance of the integrity of the local normal structures and with the health and comfort of the child. Up to this time, in a series of six consecutive cases, they have had no failures. In two patients the disease has been controlled for three years with satisfactory vision in the treated eye. The final proof in the permanent control of retinal glioma must await the time when several cases have passed the five year period.

**Ocular Complications of Epidemic Meningitis.**—Lazar encountered thirty-three cases of ocular complications of major importance in a total of 266 cases of meningitis occurring in 1933. During the early part of this year it had been customary to inject the antimeningococcus serum only intraspinally. This may have accounted for the large number of ocular complications seen during this period. About the middle of March the patients received the serum intravenously in much larger quantities. From then on during 1933 the number of ocular complications was reduced considerably. Most of the patients with the complication of paresis of the external rectus muscle still had the paresis on discharge from the hospital. Some of these

## Book Notices

**Diseases of the Air and Food Passages of Foreign-Body Origin.** By Chevalier Jackson, M.D., Sc.D., F.A.C.S., Professor of Bronchoscopy and Esophagoscopy, Temple University, and Chevalier L. Jackson, A.B., M.D., Sc., Professor of Clinical Bronchoscopy and Esophagoscopy, Temple University. Cloth. Price, \$12.50. Pp. 994, with 2,000 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

The Jacksons have added another stone to the monumental edifice they have erected in a long and brilliant career begun by the elder and collaborated in by the younger. It is a volume that should be read by every internist, pediatrician and laryngologist because it deals with problems of vital interest to all. That the spreading of this knowledge, the result of pioneering in a previously obscure field and the fruit of painstaking investigation with an enormous mass of material, is sorely needed can be justified by the startling statement of the authors that they had treated more than 400 cases of foreign bodies in the air and food passages in which the diagnosis had been overlooked prior to admission to their care. After reading this book physicians must of necessity become propagandists in the cause of prevention, since the authors in discussing etiology have shown that 87 per cent of foreign bodies gain access to the food and air tracts through carelessness. This applies particularly to the aspiration or swallowing of various objects by young children, who instinctively put everything into their mouths that their hands can grasp. This is certainly a field for the education of parents. On the subject of diagnosis the authors stress the tremendous value of proper x-ray examination in all doubtful cases of pulmonary or esophageal disease in which there is even the remotest possibility of a foreign body being present despite a negative history. Every type of foreign body that has ever been aspirated or swallowed is described with reference not only to the mode of entrance but also to the mechanism of its lodgment and the reasons for the presence or absence of symptoms as well as the pathologic changes induced. Objects of the same type in the same location produce different symptoms according to the length of their sojourn, and such cases are reviewed side by side with such clarity that the parallel once seen and studied yields a lesson that can never be forgotten. Beautiful color drawings executed by the elder Jackson illustrate these points beyond all words of description.

The problems attendant on the removal of foreign bodies are thoroughly discussed from every angle and the authors furnish the most minute details pertaining to each type and location of foreign body. Even the experienced bronchoscopist as well as the occasional operator will find this section of the book a welcome refuge in time of trouble.

Finally, the listing of 3,000 cases arranged in groups according to the nature of the foreign body with reproductions of photographs of the latter and the practical details associated with each case constitutes more than half of the volume and is a veritable storehouse of concrete knowledge which should instruct and guide the laryngologist through many a difficult situation.

**An Introduction to Psychological Medicine.** By R. G. Gordon, M.D., D.Sc., F.R.C.P., Physician to Royal United Hospital, Bath, N. G. Harris, M.D., B.S., D.P.M., Physician in Charge to Woodside Hospital, London, and J. R. Rees, M.A., M.D., D.P.H., Medical Director, Institute of Medical Psychology, London. Cloth. Price, \$4. Pp. 386. New York & London: Oxford University Press, 1936.

The term psychological medicine is used in England by several examining bodies who grant a diploma in psychological medicine (D.P.M.). This diploma is taken by medical graduates specializing in psychiatry and is elsewhere named Diploma in Psychiatry. This is therefore a textbook in psychiatry and is intended for the use of medical students. The five sections comprise psychology in relation to psychologic medicine, psychopathology, psychoneuroses, psychoses, and mental deficiency. The presentation is on conventional lines and is both clear and simple. The sections on treatment have been written in a practical way. The authors take the view that the treatment of mental illness is a subject for postgraduate study and hence they do not attempt to give details of psychotherapeutic treatment. This point of view is open to question and is somewhat surprising when one considers the emphasis being placed

by modern educators on the importance of psychiatry in the field of general medicine. With such considerations in mind, one might also have hoped that the section on psychoneuroses would have been lengthened at the expense of that on the psychoses. However, the book is in keeping with the modest number of lectures the authors suggest the students should have; that is, four or five lectures in psychology, three or four lectures in psychopathology, five lectures on the psychoneuroses, eight lectures on the psychoses, and two on mental deficiency. One must note that the two chapters covering the laws relating to mental disorders and to the legal, educational and social implications of mental deficiency apply to practices and facilities as they exist in England. As an elementary book for the medical student, the volume has many merits and can be recommended.

**The Clinical Use of Digitalis.** By Drew Luten, A.B., M.D., Associate Professor of Clinical Medicine in the Washington University School of Medicine, Saint Louis. Cloth. Price, \$3.50. Pp. 226. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1936.

President Andrew Jackson once wrote that he had sworn to uphold the constitution "as he understood it, and not as it was understood by others." Similarly, in this book Dr. Luten has presented the case for the clinical use of digitalis as he sees it. This statement must not be looked on as adverse criticism. The case is well presented; but when any one deals with so controversial a subject as this, any presentation will receive criticism in some quarters and the subject will remain controversial until the experimentalist and the clinician find some way to meet on common ground.

The book first considers the pharmacologic effect of digitalis on the heart muscle, the auriculoventricular tissues and the pacemaker. The diuretic effect, or, rather, the lack of it, blood vessel and blood pressure phenomena, and alterations in the electrocardiogram are briefly discussed. Toxic manifestations are listed. The remainder of the book, well over half of it, deals with the indications for the use of digitalis, its use in special situations, and its dosage and method of administration. Dr. Luten states that the one essential indication for the use of digitalis is congestive heart failure. In any other instance its efficacy may be questioned but never in this one. He believes that the beneficent action comes about almost wholly because of the effect on the ventricular muscle. Even in auricular fibrillation this effect plays a more important part than does the effect on the conducting tissues. He predicates this statement largely on his observation that it is almost impossible to slow the ventricular rate in auricular fibrillation when congestive failure is not present. This statement will not go unchallenged. In view of his insistence on the direct muscle action as the agent which produces the favorable result, it seems inconsistent to point out that a better result is to be expected from the use of the drug in one type of heart failure when compared with another type. He states that the response in coronary hypertensive disease failure is better than that in rheumatic disease failure. If this statement is true and his original thesis is correct, such a response would indicate only a greater destruction of muscle in rheumatic disease. The drug still affects the heart muscle and not the disease that produces the heart muscle damage.

Dr. Luten states that all evidence points to the fact that digitalis brings about an unchanged or a diminished volume output except in cases of heart failure. This observation does not fit in with his willingness to use digitalis in instances in which no failure is present but its onset may be suspected. In no place does he mention the irritant action of digitalis except as a toxic phenomenon. It has been suggested that digitalis should be used with caution in those instances in which the heart muscle is inclined toward excessive irritability. Dr. Luten apparently does not subscribe to this view. All these differences of opinion are at once forgotten when the chapters on dosage and administration are read. If one decides to give digitalis, one needs only to read the advice given here and the treatment will be correctly carried out. The book may be read with profit by all students and practitioners and will be especially valuable to those who have not had the opportunity to follow the recent voluminous literature dealing with the subject.

normal value was approximated. These observations indicate that the products of tissue protein catabolism can be utilized in the formation of new serum protein. The experimental production of what seems to be an inhibition of the serum protein regenerating mechanism suggests that the most profitable line of approach to solution of the problem of hypoproteinemia lies not so much in the evaluation of dietary factors as in finding a way for stimulating internally the serum protein regenerating mechanism, which seems to involve in some manner the capacity of the tissue to furnish protein for the needs of the plasma.

- Further Studies on Relation of Heterophile Immunity to Incidence of Colds. G. E. Rockwell and H. C. Van Kirk, Cincinnati.—p. 417.

**Interpretation of Schick Tests.**—Brandon and Fraser determined whether there was consistent agreement between the reactions to different Schick products of licensees of the Treasury Department of the United States. Of the eighty-seven individuals Schick tested each with six different products, thirty (34 per cent) showed inconsistencies and twenty-three (26 per cent) showed frank disagreement in the readings. Reactions to the toxins of the Schick outfits were remarkably consistent with the exception of one product. Errors in interpreting the "Schick immunity" were usually due to the inconsistent reactions ensuing on the Schick control. False interpretations of the Schick test are made most frequently in the group of persons skin sensitive to diphtheria protein. Products containing dilute toxoid as a Schick control were the only ones that resulted in no errors of interpretation of the Schick immunity of the persons tested. All products using heated toxin as a control gave some false results. The observations substantiate the fact that the antitoxin level of Schick immunity lies between 1/500 and 1/250 of a unit of antitoxin, when the Schick test material conforms to the standard recommended by the League of Nations.

- Toxic Dusts and Fumes. L. T. Fairhall, Boston.—p. 668.

**Study of Heat Disease.**—Heilman and Montgomery present thirteen cases of heat disease (six of heat cramps, three of heat exhaustion, three of heat retention and one of mixed cramp

and exhaustion) selected as the most severe clinical forms of heat disease from a total of 184 cases. Heat regulation must be considered from the mechanism of heat production and of the factors involved in the control of heat production and from the mechanism of heat dissipation and of the factors involved in this process. Sensitiveness to external heat varies greatly in different individuals and may be increased by fatigue, alcohol, rich protein diet, gastro-intestinal disorders and particularly circulatory disease. Continued exposure to heat frequently appears to increase tolerance, but this may be explained for the most part by conservation of energy, increased muscular efficiency and more intelligent food intake. But there also are individuals in whom exposure to excessive heat of the sheet floor breaks down tolerance to heat, and symptoms of heat disease result. The heat retention cases were pathologic in that they did not react to the environment of the sheet floor in a physiologic manner. This failure of normal perspiration and heat regulation resulted in heat retention. The heat cramps and heat exhaustion cases differed from the control group of steel workers only in the severity of dehydration and chemical changes in the blood. It is rational that the failure of the thermolytic center causes an underactivity of heat dissipation and the excess heat is retained and accumulates to the point of producing clinical signs and symptoms. When the temperature exceeds 98.3 F., loss of heat by radiation and conduction ceases and external regulation of the body temperature depends solely on convection and evaporation of perspiration. The men who suffered with heat retention came to work, perspired profusely for a short time, usually only a few hours, and then ceased to sweat, while others came to work and could not perspire on the day they were admitted to the hospital suffering with heat retention.

**Quantitative Determination of Cyclopropane in Blood.**—Robbins studied the concentrations of cyclopropane in the blood necessary for anesthesia or for death. The method used was a slight modification of that used by Haggard and Greenberg for ethyl alcohol. The distribution ratio of cyclopropane between water and air over a temperature range of from 20 to 45 C. and that between blood and air over a temperature range of from 20 to 40 C. has been determined. The solubility of cyclopropane in the blood of the human being and the dog is

products and bacterial biologic products. The author has recognized the various changes that have taken place in pharmacognosy as well as those which have been incorporated in the latest editions of the United States Pharmacopeia and the National Formulary. The volume is of value to drug analysts and collectors of crude drugs and is an excellent work of reference for the physician who may desire information concerning the characteristics and constituents of crude drugs.

**Medicine and Mankind. Lectures to the Laity Delivered at the New York Academy of Medicine.** Edited by Iago Galdston, M.D. Introduction by Eugene H. Pool, M.D., President, New York Academy of Medicine. Cloth. Price, \$2. Pp. 217, with 6 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1936.

A listener has frequently come away from a meeting enthusiastic about the principal speaker. In his enthusiasm he has expressed a wish that if he could but have a copy of the lecture he has just heard it would serve as an inspiration as well as excellent reading during leisure moments. In this book the listener's wish has been granted. A series of lectures that have been given at the New York Academy of Medicine has been brought together. The names of the various speaker-authors are well known and command respect. Their abilities are recognized and well established and require no comment. The reviewer was left with a feeling, on completing the book, that there was something lacking, something gone from each lecture so that the reader, unlike the listener, had no exceptionally great desire for a copy of the "speech" nor had he any particular wish to hear the speech itself. The "something lacking" is the author. It is the author, or rather speaker, that puts across a talk. When that talk is transferred to the page it all too often produces little inspiration and falls into the class of just another bit of history.

**Oxidation-Reduction Potentials in Bacteriology and Biochemistry.** By L. F. Hewitt, Ph.D., B.Sc., F.I.C., Biochemist at the Belmont Laboratories, Sutton, Surrey. With a foreword by the Medical Officer of Health. London County Council, No. 3200. Fourth edition. Paper. Price, 2s. Pp. 101, with 27 illustrations. London: P. S. King & Son, Limited, 1936.

The theoretical considerations of oxidation-reduction potentials are identical with those given in previous editions. Apparatus and methods described are essentially the same as in former editions. A thermionic valve electrometer circuit for the measurement of biologic potentials is described briefly. The charts of dye indicators for potential measurements are increased in size and are evaluated to  $pH$  7. Studies on tumors, tissue cultures and yeast preparations have been added to the section on systems of special biologic interest. The section on bacteriologic applications has been brought down to date. Note is made of vitamin-like growth accessory substances and oxidation-reduction potentials in the making of cheddar cheese. New data are given on the potentials produced by members of the *Salmonella* and nonsporulating anaerobe groups. The monograph furnishes an excellent source of references for more detailed reading.

**How We Came by Our Bodies.** By Charles B. Davenport. Cloth. Price, \$3.75. Pp. 401, with 236 illustrations. New York: Henry Holt & Co., 1936.

The title is intriguing and would make the average reader-parent pick up the book. But he would put it down soon as being a little too difficult, a little too technical for his "average intelligence." As a textbook for college students it can be recommended. Even the average reader-parent will need a guide or instructor to help him. The author presents his subject in three parts. The first is the development of the single cell into the adult human being. The second part discusses in detail the structure of the cell, how the cells become differentiated, and the part played by heredity, genes, tramp cells and their migration. A chapter entitled "Meeting Stresses and Accidents" discusses twins, as well as making embryos develop abnormally. The third part deals with the origin of the various parts of the machinery of development. It deals with the genes and the mechanism by which they have been handed to us. Then the author discusses bacteriophages, mutations, cephalic index and albinism, as well as mutations in metabolism and hair length, blood groups and eye color. The physician today is concerning himself with sex education to a greater degree than formerly. He is constantly seeking aids

for this purpose. This book is not one that he can take from his shelf and hand to a harassed parent who is seeking an answer to the question just how do you have a baby? Cross sections of the Haversian system of a macerated human hip bone won't help him any more than tangential section of ramie fibers showing dextrose units.

**At the Point of a Lancet: One Hundred Years of the Canton Hospital, 1835-1935.** By William Warder Cadbury, A.M., M.D., F.A.C.P., Superintendent of the Canton Hospital, and Mary Hoxie Jones, B.A. Cloth. Price, \$2; 10s. Pp. 304, with 13 illustrations. Shanghai: Kelly & Walsh, Limited, 1935.

The figurative title of this work does not indicate its actual purport. The subtitle is, however, a statement of the real nature of the book. The volume is a record of one hundred years of the work of the Canton Hospital, an institution which has had a notable career in China, contributing not only to the actual care of the sick but also to the advancement of medical science. Among the graduates of the school at Canton was Dr. Sun Yat-sen, famous statesman of China, who died of cancer on March 12, 1935. Particularly interesting are the biographies of some of the famous persons associated with the school and the hospital. Dr. Cadbury in his concluding chapter indicates his belief that there will always be a future for the foreign doctor in China, particularly as the expert who opens up fields in a way in which only the missionary doctor can function.

**Diseases of the Eye.** By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., Consulting Ophthalmic Surgeon, University College Hospital, London. Eighth edition. Cloth. Price, \$5.50. Pp. 705, with 381 illustrations. New York: Macmillan Company, 1936.

The first edition of this justly popular textbook of ophthalmology was published in 1907 and public demand has forced the author to this, the eighth, edition, not including reprinting of the fourth and sixth editions. The difference between this and the previous edition can be best given in the words of the author which form the preface:

Though no very radical changes have been made in this edition and the same care has been taken to retain the relative importance of details so that the student and medical practitioner may view them in their proper perspective, it has been thought advisable to refer briefly to some modern advancements in treatment, such as the detached retina. Further, although the time is not yet ripe for estimating the future practical value of physiological and biochemical researches, some of them have been of such outstanding significance that it was deemed wise to draw attention to them. Among these one may mention the rôle of chemical substances, e. g., histamine and acetylcholine, in nerve stimulation, axon reflexes, vitamins, and viruses. Very encouraging advance has been made in our knowledge of the biochemistry of the lens, though it would be premature to assess its value for the etiology of cataract.

For the medical student and for the general practitioner, this book is of inestimable value, which is enhanced by the excellent illustrations. It is written by a master of ophthalmology and is based on his long practical experience.

**Psychiatrische Vorlesungen für Ärzte.** Von Prof. Dr. Kurt Schneider, Direktor des Klinischen Instituts der Deutschen Forschungsanstalt für Psychiatrie (Kaiser Wilhelm-Institut) in München. Second edition. Boards. Price, 6.20 marks. Pp. 195. Leipzig: Georg Thieme, 1936.

This compend discusses schizophrenia, cyclothymic psychosis, psychopathic personality, neurasthenia, hysteria, abnormal life reactions, mental abnormalities of children and young adults, suicide, psychosis due to internal diseases, brain diseases and epilepsy, psychiatric symptomatology and diagnosis, and psychiatric management. In an appendix Schneider discusses psychiatric system and structure of the psychosis as well as the diagnosis of schizophrenia and manic depressive insanity. The style is difficult because of the long and rather difficult structure of its sentences. There is an abundance of superfluous discussion. The bibliography is small.

**Das Ärztebüchlein: Eine Sammlung besinnlicher Worte für die Feierstunden des Arztes, zugleich ein Ratgeber für die tägliche Praxis. Unter Mitbenutzung hinterlassener Aufzeichnungen Erwin Lieks. Von Walther Klusmann. Mit einem Geleitwort von Prof. Dr. Klare.** Cloth. Price, 4.80 marks. Pp. 199. Leipzig: Georg Thieme, 1937.

In this volume the author has collected quotations from a great mass of literature, largely German but also classical, dealing with the physician. It is classified according to the philosophical contributions, the art of medicine, the fee and similar topics.

scopically, have already shown special new aspects which will be of great importance in histologic examinations. The method enlarges the domain of medical histology. It introduces new elements in the physical and chemical nature of cellular constituents. Absorption zones correspond to regions of small atomic weight, and vice versa. This new process will make possible information on the density of cellular constituents. With the aid of a new chemical agent it will be easy to render opaque a particular cellular region and to study it better, as color does not play a part here; the range of useful agents being greater and at the same time the technic being much more simple, the field of histochemistry will be enlarged.

#### Effect of Drugs on Different Segments of the Intestine.

—Of double strength solution of posterior pituitary, physostigmine, peristaltin and acetylcholine as stimulants of the tone and motility of the human intestine, Guthrie and Barger found solution of posterior pituitary alone to be a marked stimulant of the human intestine. It is the only drug of the group that is likely to prove effective regularly as a therapeutic agent in augmenting the peristalsis of an atonic or paralyzed intestine. The effect on the intestine that was observed to follow every administration of solution of posterior pituitary was so constant that the authors feel justified in concluding that the drug (1) is a powerful stimulant of intestinal peristalsis, (2) is consistent and regular in its action, (3) acts with apparently equal strength on both the colon and the ileum, (4) increases the motility of the intestine without apparently exerting any effect on the tonus and (5) is rapid in its action. Following its administration, it acts within three to five minutes and its action extends, with gradually diminishing effect, for from three-fourths to one and one-half hours. Physostigmine and peristaltin were found to be inconstant and uncertain in their action. The peristaltic contractions which each of these drugs produced were relatively mild, less regular in their occurrence and totally lacking in propulsive force as compared with those that followed each injection of solution of posterior pituitary. Acetylcholine possesses little worth as a stimulant of the human intestine.

On seven of the nine occasions on which the drug was employed in doses ranging from 100 to 400 mg., no evidence of any effect on the intestine was apparent. On the two occasions on which some increase in either the tone or the peristaltic activity of the colon and the ileum was observed to occur, the stimulative effect of the drug was relatively slight and insignificant, as well as transient in character.

**Localization and Extraction of Foreign Bodies.**—Ellis proposes a method of localization of foreign bodies that can be carried out in any hospital provided with x-ray equipment and an operating room. Suitable right angle wire screens can be made in a hardware store. The patient is placed on the operating table and fastened to prevent movement. The skin is sterilized and the sterile right angle screen is fastened to the part by a half hitch with tape or cord. A roentgenogram is taken of each side of the wire screen with the tube centered and the "normal ray" at right angles to the flat surface of the screen. The distance of the tube should be a meter or more, if this is practical. From these roentgenograms the surface localization can be determined accurately by counting off the interstices of the metal screen on the x-ray image and on the skin. The foreign body is outlined on the skin with a dye or metal points, which are left in place until the operative incision is made. The depth can be measured on the roentgenogram of the other surface of the screen. A fine needle of appropriate length, as measured on the metal screen, is introduced through the surface projection of the foreign body on one plane of the screen and at right angles to it. Thus the approach to the foreign body is easily made. A few drops of colored opaque oil are introduced at the site at which the foreign body is expected to be located. As the needle is withdrawn a fine trace of colored oil is left along the path by gentle pressure on the syringe. This may serve as a guide in the surgical approach to the deeply injected oil. Another set of roentgenograms is taken and the relation of the colored radiopaque oil to the foreign body can be determined. If the first attempt is not successful and the deposition of oil is not in close proximity to the foreign body, the operation can be postponed for a few days until the oil is dispersed and another attempt to obtain internal localization by means of the oil can be made. General anesthesia is preferred, as local anesthesia often distorts the topography of the part. Before the skin incision is made and as each fascial plane is approached, points on each side of the contemplated line of incision are seized with Allis forceps and lifted so that the pressure of the knife will not displace a movable body beneath. Wide exposure and a minimum of sponging is desirable. A single foreign body can be found in the colored oil. A collection of minute fragments or an encapsulated body can be removed by dissecting the colored mass entirely.

**Transfer of Tumor Cells by the Surgical Knife.**—Saphir examined the material that adheres to the blades of knives used for obtaining biopsies of tumors, particularly breast tumors. The knives with which various types of malignant tumors were incised were examined shortly after they had been used. Either direct smears were made from the respective blades or the blades were washed with a small quantity of saline solution and smears were made from this suspension. Invariably, smears made from the material on the knives used to cut through the tumors showed tumor cells. In some instances the tumor cells were so abundant that at low magnification their numbers were comparable to that of erythrocytes on a blood smear of average thickness. Also, smears that were made from material on the knives used for removal of the primary tumor for biopsy before the radical breast operation was performed showed tumor cells. It appears that every biopsy carries with it the danger of transferring, and possibly transplanting, tumor cells into healthy tissue.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

- \*Cardiodynamic and Electrocardiographic Changes in Normal Pregnancy. H. Landt and J. E. Benjamin, Cincinnati.—p. 592.

**Electrocardiographic Changes in Pregnancy.**—Landt and Benjamin observed nineteen normal pregnant women throughout the course of their pregnancy and puerperium. The study included the correlation of clinical, cardiodynamic and electrocardiographic changes. The final examination (control) was taken approximately two months after delivery. The study indicates that pregnancy definitely places a burden on the cardiocirculatory system. In the normal woman this burden can be compensated by calling on the reserve capacity of this system. The method of compensation is both mechanical and physiologic in nature. The electrocardiographic changes observed during the course of pregnancy may be interpreted definitely on the basis of mechanical shifting of the heart. This shifting of the heart produced a left axis deviation in the electrocardiogram of the majority of the patients studied. The normal woman who does not develop any untoward signs or symptoms during the course of pregnancy shows a normal clinical, cardiodynamic and electrocardiographic picture from six to eight weeks after delivery.

**Diagnostic Value of the Frei Reaction.**—The confidence of D'Aunoy and von Haam in the reliability of the Frei test has been justified by numerous cases in which animal inoculation confirmed the results of the Frei test while the clinical and biopsy diagnoses failed to reveal the true nature of the condition. During the last two years they have performed more than 1,697 Frei tests on patients with or without inguinal lymphogranuloma. Diagnosis based on the test proved correct in 90.9 per cent of 547 cases; 7.2 per cent doubtful reactions were obtained, and in 1.9 per cent apparently faulty reactions

occurred. Syphilis as indicated by positive blood Wassermann reactions was present in 19.5 per cent of Frei positive cases and in 22 per cent of Frei negative cases. Acute gonorrheal and chancroidal infections were present in about 10 per cent of the Frei positive cases. Comparison of the various antigens used for the Frei test showed that antigen prepared from human gland and brain emulsions of experimentally infected marmosets give fewer doubtful reactions than do antigens prepared from diluted pus of human lesions and brain emulsions of infected mice. These results demonstrate the marked degree of specificity and the high diagnostic value of this cutaneous reaction in the recognition of inguinal lymphogranuloma in its various manifestations. The fact that 17.4 per cent of Negro patients applying because of various conditions to the Charity Hospital of Louisiana gave a positive reaction demonstrates the wide distribution of the disease among the Negro race in that locality.

**Diagnostic Significance of Antidysentery Bacteriophage.**—Mackie is not impressed by the incidence of specific bacteriophage in association with chronic bacillary dysentery. Only 29 per cent of the cases with acceptable evidence of infection by *Shigella dysenteriae* exhibited a lytic principle action against these organisms. An antidysentery bacteriophage was found accompanying positive culture in only 34.7 per cent of eighty-four cases. Moreover, his experience leads him to question seriously the specificity of such a lytic principle. A bacteriophage active against his laboratory strains was obtained in 12.8 per cent of eighty-six control cases. None of these could be suspected of infection by *Shigella dysenteriae* on cultural or serologic grounds, and, with the possible exception of the cases of chronic ulcerative colitis, none could be suspected on clinical grounds. Antidysentery bacteriophage has been found in the control cases in association with such diverse conditions as achlorhydria, acute appendicitis, arspenamine hepatitis, foreign body in the liver, intestinal protozoal infection and chronic ulcerative colitis. The clinical and bacteriologic significance of antidysentery bacteriophage in chronic intestinal infections is not as yet sufficiently well defined to justify the term "diagnostic bacteriophage."

**Specific Food Sensitiveness.**—Alvarez believes that food sensitiveness should be looked for carefully whenever the symptoms of abdominal distress point to the presence of an oversensitive colon, when they are vague or unusual or whenever careful examination fails to reveal any sign of disease in the duodenum, stomach, gallbladder or appendix. The diet must be studied in every case of true flatulence or bloating, and food

true tuberculous arthritis. They cannot categorically deny the possible influence of associated visceral tuberculosis on the production and course of the joint disease, but they do not use the term "tuberculous rheumatism" because every case pursued a course consistent with nonspecific arthritis and immobilization treatment, adopted because the condition was suggestively tuberculous, proved to be a totally unsuitable procedure in each case. The cases have been utilized to illustrate the difficulties in the early diagnosis of tuberculous arthritis and to warn against the too ready acceptance of a tuberculous etiology in multiple arthritis occurring in presumably tuberculous subjects. The many factors that contribute to the confusion in diagnosis in the case of a multiple arthritis are (1) the insidious monarticular onset of some case of multiple nonspecific arthritis, (2) the coexistence in the patient of some visceral tuberculous lesion, which may or may not influence the course of a non-tuberculous polyarthritis, (3) the possible occurrence of a single tuberculous joint superimposed on a nontuberculous multiple arthritis, (4) the occasional incidence of true tuberculous arthritis in two or more joints, (5) the comparative infrequency of nonspecific arthritis of the hip in patients under middle age and the tendency to suppose such a condition to be tuberculous, (6) modification of the course of nonspecific arthritis due to early immobilization and (7) the possibility that there exists an atypical tuberculous form of polyarthritis—tuberculous rheumatism. Expectant treatment should be adopted in all such cases. This should consist of maintenance of general hygiene and rest in bed without immobilization until unequivocal evidence of the tuberculous or nontuberculous nature of the joint disease appears or is obtained by examination of aspiration or biopsy material.

 The Eynesbury Quadruplets: First Nine Months of Life. E. H. Harrison.—p. 917.

**Alkali Poisoning.**—Cope calls attention to the occasional toxic effects of alkaline powders which, in various mixtures, are prescribed and sold as "stomach powders" for the relief of gastric ulcer and similar complaints. Some persons are abnormally sensitive to some constituent of the alkaline powders and chronic alkali poisoning may persist for several weeks without the nature of the condition being appreciated unless its possibility is borne in mind. The condition develops typically in sufferers from gastric ulcer or similar gastric disorders. During the early stages of the development of symptoms a marked deterioration in appetite is frequent, especially an antipathy to the taking of milk, associated with attacks of vomiting of moderate severity. The most typical symptoms are concerned essentially with a change in the character of the patient, including thoughtlessness, irritability, unreasonableness, melancholy and depression. These symptoms continue, as a rule, to increase in intensity until definite drowsiness appears. There may be complaint of vague headaches and of general muscle pains. Somnolence and drowsiness become an increasingly prominent feature, until finally the patient may even pass into coma. In acute cases the transition from apparent normality to definite drowsiness may take only a few days; in chronic cases the patient may remain for weeks in a state of depression and mental inefficiency without the appearance of any drowsiness. Soreness of the eyes is complained of, owing to a red and inflamed conjunctiva. The physical signs of alkali poisoning are scanty. The most important changes are to be found in the blood. There may be (1) a severe degree of nitrogen retention, (2) a definite uncompensated alkalosis and (3) hypercalcemia and hypermagnesemia. Since the characteristic symptoms of alkali poisoning are referable to change in the mental state, a previous knowledge of the patient and his character is of the greatest help in early diagnosis. Although alkali poisoning does not itself cause a rise of blood pressure, the presence of this or of other signs associated with

chronic nephritis does not eliminate the diagnosis. The essential and often the only necessary point in treatment is to stop the administration of all alkalis. Citrate is to be classed as an alkali and should not be given in ulcer patients. Recovery involves the elimination of retained bicarbonate, the restoration of a normal blood reaction and the restoration of normal renal function with resultant elimination of retained products of nitrogen metabolism. It is possible that the hydrated magnesium silicate introduced recently will solve the problem of the treatment of gastric ulcer in persons who are sensitive to alkalis.

**Roentgen Examination of Gastro-Intestinal Tract.**—O'Connell suggests using a narrow diaphragm with the patient in the right anterior-oblique position; the patient is asked to swallow one mouthful of barium sulfate with tragacanth, the passage of the barium through the esophagus is observed, the tube and screen are shifted and the entrance of the barium into the stomach is observed. Its method of entry and its passage along the lesser curvature are watched closely. If the barium is slow in proceeding down the stomach, the patient is asked to take one or two deep breaths. He is then rotated to face the operator directly. The cardiac end of the stomach is observed closely, and attention is then directed to the pyloric end. General observations as to the presence of a large quantity of secretion, filling defect or ulcer niche are made. The patient is then advised to relax somewhat and to slacken his abdominal muscles, and with the gloved hand the whole mucous membrane of the stomach—except that of the cardiac end—is displayed on the screen. If a suspicious area is seen, the diaphragm is narrowed and a whole plate or 10 by 8 film is exposed. If the gastric mucous membrane relief is normal, the examination is continued without delay. For the examination of the duodenum, some of the original mouthful of barium is forced into the duodenal bulb. With the tips of the fingers the barium is massaged over the lining of the bulb, the patient being rotated into different positions to achieve this. These observations having been made under the screen, a 10 by 8 film of the stomach and duodenal region is exposed. The patient is then given four or five further mouthfuls of barium sulfate and instructed to swallow these immediately. The stomach is observed again to detect the presence or absence of peristalsis. One or two waves are watched until they reach the pylorus, and anomalies are observed. Barium is already filling the bulb or it may have to be forced into the latter under the pressure of the hand. If this method fails to fill the bulb, the patient finishes the half pint of barium. The bulb is again watched in its filling and emptying and any persistent change of shape is seen. Observation is taken in both oblique directions and two whole-plate films are exposed. The second and third stages can be seen easily during this examination of the bulb. Finally, the actual shape and position of the stomach are observed. The level of the lower pole is ascertained. The patient, still fasting except for the half pint of barium, returns in two hours and further screening is carried out to ascertain whether the stomach is empty or how much barium remains in it. The patient is then allowed to return to bed or go home and have a meal. He is asked to return next day, having had his breakfast. Under the screen the position and mobility of the cecum, which always contains barium, are noted. One notes

patients were later observed in the clinic for patients with diseases of the eye. The paresis cleared up completely. During 1934, among ninety-eight patients with epidemic meningitis six ocular complications were observed. Every third patient received meningococcus antitoxin by vein. Aside from the fact that the epidemic was mild as compared to that of 1933, none of the patients who received the antitoxin showed intra-ocular complications. Those receiving the serum did. During 1935 only five ocular complications were observed in 211 cases of epidemic meningitis. Most of the patients were then receiving the antitoxin intravenously, and a few spectacular recoveries from intra-ocular complications were observed. From the observations made there appears to be no doubt that ocular complications of epidemic meningitis are due to an infection of the blood stream, reaching the posterior segment through the retinal or choroidal vessels, or both. The two major ocular complications are endophthalmitis and paresis of the external rectus muscles. Treatment of the disease with an antitoxin has reduced greatly the number of ocular complications. Local treatment is without avail, once the posterior segment has become involved. This is especially true when the serum is employed. Microscopic examination in cases of endophthalmitis complicating epidemic meningitis shows nothing that distinguishes the condition from endophthalmitis due to other blood-borne infections.

### Arch. of Physical Therapy, X-Ray, Radium, Chicago

17: 673-736 (Nov.) 1936

- \*Short Wave Diathermy in Heating of Human Tissues. J. S. Coulter and S. L. Osborne, Chicago.—p. 679.
- Ultrasound Wave Diathermy in Pyogenic Infections. W. J. Egan, Milwaukee.—p. 688.

- Physical Therapy Procedures in Otolaryngology. E. G. Linn, Des Moines, Iowa.—p. 708.
- Some Physical and Clinical Aspects of Ultrashort Waves. C. K. Gale, New York.—p. 712.

**Short Wave Diathermy in Heating Tissues.**—Coulter and Osborne emphasize that experiments on phantom model and on dead animal tissues cannot be used to prove the effects of short wave diathermy on living human tissues. Experiments on twelve medical students confirmed previous studies that there were no significant differences of one wavelength over another within the range of 6 to 25 meters in the heating of live human muscle and fat tissues. Under aseptic precautions a nonmagnetic nonconducting sheath was inserted subcutaneously and into the quadriceps extensor muscle. The intensity of the current was governed by the patient's comfort. There were no significant differences in the use of 6, 12, 15, 18 and 24 meter wavelengths when using the cuff technic of the electric field method, and no significant differences in the use of 12, 18, 24 and 25 meter wavelengths when using the coil technic of the electromagnetic field. In the studies of tissue heating with air-spaced electrodes with the electric field the efficiency of heating is dependent on the size of the electrodes, the energy available from the apparatus, the method of application, the distance of the electrodes from the skin and the patient's tolerance (comfort).

**Vitamin D and Fever Therapy in Chronic Arthritis.**—Livingston treated twenty-two patients having severe arthritis of various types with from 200,000 to 600,000 international units daily of vitamin D only or with vitamin D and weekly fever therapy. Nineteen patients showed clinical improvement, one discontinued the treatment and two showed no improvement. Former observations revealed that fever therapy alone was not effective. Fever therapy when employed in conjunction with vitamin D caused more rapid clinical improvement than vitamin D alone. When toxic symptoms appear, the drug should be discontinued at once for two weeks. So far as could be observed, there is no contraindication to this form of therapy. The blood chemistry and blood picture remain within normal limits with the exception of a decreased sedimentation rate and a shift in the Schilling test toward the right. Arthritis is probably associated in part with a vitamin D deficiency. The mechanism of this therapy is not understood.

### Arkansas Medical Society Journal, Fort Smith

33: 117-134 (Dec.) 1936

- \*X-Ray Therapy in Infections. D. A. Rhinehart, Little Rock.—p. 117.
- Present Status of Vaccine and Serum Therapy in Acute Contagious Diseases. A. G. Cazort and J. N. Compton, Little Rock.—p. 119.

**Roentgen Therapy in Infections.**—Rhinehart mentions a case of carbuncle, thyroiditis and unresolved pneumonia in which roentgen irradiation proved efficacious. To these three cases he could add any number showing the beneficial effects of radiation therapy in the treatment of acute and chronic infections. Furuncles and boils in any region usually respond promptly to a single short roentgen treatment. Unless the patient is diabetic, roentgen treatment of a carbuncle in any locality usually gives a spectacular result. Acute infections in the lymph nodes of the neck following an acute tonsillitis or an acute infection of the upper part of the respiratory tract in children respond to one or two treatments. In spite of the benefits following this form of therapy, the exact action is yet empirical. In the radiation treatment of acute infections, the doses are always small. In acute conditions often a single application is sufficient. If not, the treatment may be repeated two or three times at intervals of two days. In chronic infections the period of treatment must be more prolonged; usually weekly treatments are given until beneficial results have been obtained. Because of the small amounts of radiation that are used, there is no danger of damage to any of the normal tissues, and permanent skin damage does not occur.

**Influence of Diet on Regeneration of Serum Protein.**—By quantitative plasmapheresis, Melnick and his associates investigated the effects of single proteins in artificial synthetic diets with respect to their value in promoting the regeneration of serum protein. The ratio of the amount of serum protein per week removed by bleeding above that regenerated by the dog, when eating the protein-free diet, to the dietary protein increment (i. e., above that required for nitrogen equilibrium) was termed the potency ratio. The results indicated that serum protein was slightly superior to casein and lactalbumin in promoting the regeneration of serum protein. However, the respective potency ratios, varying from approximately 0.51 to 0.36, were comparable and not widely divergent to those reported by others. Whereas in some individuals dietary proteins may be able to produce a significant increase in the serum protein concentration, the potency ratios are not sufficiently different to warrant the administration of any one protein in preference to another. The inhibitory effect of the basal protein-free diet with respect to serum protein regeneration in the dog was demonstrated also by the inability of the protein concentration to attain the normal level in spite of discontinued plasmapheresis. However, a subsequent fasting period resulted in a progressive rise in the serum protein concentration until the

\*Sodium and Water Metabolism in Relation to Disturbances of Carbohydrate Metabolism After Adrenalectomy. F. Verzár and L. Laszt.—p. 844.

Biosynthesis of Ascorbic Acid. G. C. Guha and B. Ghosh.—p. 844.

**Disturbances of Carbohydrate Metabolism After Adrenalectomy.**—Verzár and Laszt have found that, in the absence of the adrenal cortex, acriflavine hydrochloride is not transformed to acriflavine phosphoric acid but that adrenalectomized animals can be kept alive with large quantities of the latter substance (vitamin B<sub>2</sub>). Lack of adrenal cortex causes serious disturbances in intermediate metabolism of carbohydrates and fats, particularly in the absorption of these substances. The selective absorption of dextrose is inhibited after adrenalectomy, and this is due to the absence of the cortex, since it can be restored by administering adrenal cortex extract. In adrenalectomized rats, the ingestion of dextrose causes great losses (into the intestine) of sodium by diffusion and of water by osmosis. Therefore the adrenalectomized animals, in contrast to normal rats, develop intensive diarrhea after dextrose administration. This is also seen in normal animals after the administration of xylose, which is absorbed slowly, or after dextrose with iodoacetic acid poisoning, when the dextrose is also absorbed slowly. The inhibition of the selective absorption of dextrose in adrenalectomized animals leads secondarily to losses of sodium salts and water. Similar disturbances are possible in the intermediate metabolism of carbohydrates and fats. These secondary disturbances of loss of sodium and water may be the cause of death of adrenalectomized animals, which can be prevented by giving sodium salts. In several cases, rats adrenalectomized from eight to fifteen days before died in from three to five hours when 5 cc. of a 50 per cent solution of dextrose was fed by stomach tube. A second group of such rats survived when sodium chloride and carbonate were given simultaneously.

Gaucher's Disease. T. F. Bloem, J. Green and C. Postma.—p. 517.

**Subarachnoid Hemorrhage.**—Taylor and Whitfield base their study on eighty-one cases found by investigating the records of two general hospitals. Although subarachnoid hemorrhage is generally recognized as the commonest cerebral vascular accident of young persons, half of their cases occurred in patients more than 40 years of age. Fifty-one of the patients are dead and twenty-one were known to be alive in 1934, while nine could not be traced. Age did not appear to be a decisive factor in deciding the issue of death or recovery. The onset of symptoms ranges from sudden unconsciousness to mild headaches, while occasionally isolated neurologic signs without any generalized effects are the first indication of the condition. The classic onset with sudden unconsciousness was elicited in two thirds of the cases. On reaching the hospital forty-three of the patients were still unconscious, thirty-seven were conscious and one was dead. The mental state was abnormal, apart from unconsciousness, in eighteen patients, ranging from actual delirium to lesser degrees, such as incoherence, disorientation, irritability and confusion. Fits occurred in sixteen patients, usually either at the onset and did not recur, or associated with a terminal relapse as though there had been a further leakage of blood, which soon proved fatal. Signs of meningeal irritation are probably constant in subarachnoid hemorrhage when the leak is appreciable and sufficiently recent. Generalized rigidity with extension of the limbs was a characteristic feature in a number of cases. In many cases more particular neurologic signs were noted, which were sometimes of value in localizing the position of the aneurysm. Ocular palsies were frequent

but of no localizing value. In cases in which a raised blood pressure was found, it was obviously due to a sudden increase in intracranial pressure, but in some patients, especially these in middle and later life, high blood pressure may have existed before the onset of subarachnoid hemorrhage and may, in association with arterial degeneration, have been a cause and not an effect of their ruptured blood vessel. The temperature was subnormal immediately following the hemorrhage in all cases (often 95 F.). If the patient lived as long as twenty-four hours after the onset of hemorrhage, some degree of pyrexia always occurred. Lumbar puncture is the most valuable diagnostic aid. The cerebrospinal fluid is intimately mixed with blood and, when the corpuscles are allowed to settle, the supernatant fluid remains yellow. The explanation of the rare cases of subarachnoid hemorrhage with clear fluid at lumbar puncture is that the puncture is done before the blood has had time to get down to the lumbar theca or that the sudden rush of blood from a ruptured aneurysm causes such a sudden increase of intracranial pressure that a pressure cone forms and prevents the blood from traveling down to the spinal theca. Apart from the increase in protein due to the presence of blood, the chemistry of the cerebrospinal fluid is usually unaltered, though sometimes the chlorides vary. Necropsies were performed on forty-three patients and a ruptured aneurysm was found in thirty-three on or close to the circle of Willis; in eight cases the source of the hemorrhage could not be localized and in two cases a vessel had ruptured but no evidence was found of an aneurysm. The prognosis is always serious—an immediate mortality of 63.4 per cent was found—and because of the antagonistic forces that result from the ruptured cerebral vessel treatment is necessarily restricted in its usefulness, but the judicious and cautious use of lumbar puncture is of the utmost value, and the partial replacement of the cerebrospinal fluid by air has been tried in these cases and is suggested as a helpful adjunct.

\*Degenerative Myositis from Melitensis Infection: Report of One Case. A. F. O'Donoghue and W. Scott, Sioux City, Iowa.—p. 462.

**Degenerative Myositis from Melitensis Infection.**—O'Donoghue and Scott report a case of degenerative myositis in a farmer, aged 25, who, when first seen, complained of pain in the back which he stated began a week before, following a mild angina. The pain, he stated, was of a deep burning type and practically constant. The oral temperature reached 102 F. on several occasions, but there had been no chills. Other symptoms complained of were anorexia, lassitude and periodic mental confusion. Examination showed that the deep muscles of the back were in spasm, and there was tenderness along the entire dorsal and lumbar regions with restricted motions in all directions. Agglutinations for Malta fever were positive in dilutions of 1:320. The intradermal reaction to Malta fever likewise was strongly positive. A diagnosis of Malta fever spondylitis was made, the patient was hospitalized and 50 cc. of convalescent goat serum was given intravenously. Brucellin injections were begun four days later and continued every three days for ten doses. The patient began having severe pain in both shoulders, which radiated downward to the deltoid tubercles. This continued for one week and then disappeared. About five weeks later the patient noticed that the scapulae were becoming more prominent and that the shoulder motions were becoming weak. Reexamination showed a marked atrophy of the supraspinatus and infraspinatus muscles and of the deltoids to a moderate extent. Abduction and external rotation were diminished, but there were no actual paralyses present. The forearms were strong and showed no signs of wasting or of sensory impairment. A biopsy from the right infraspinatus muscle showed a very marked degeneration of the muscle fibers with interstitial round cell infiltration. Cultures from the muscle remained sterile after ten days. Physical therapy was instituted, but improvement could not be noted. The patient was again hospitalized and placed in the inductotherm, and good thermal reactions up to 105 F. for eight hours were obtained on three occasions. A checkup three months later revealed that all pain and tenderness had disappeared, all motions of the shoulder were powerful, the spine was limber and the muscles over the scapulae had filled out remarkably.

**Bromide Delirium.**—Levin bases his discussion on thirty-four cases of bromide delirium that occurred in 1,399 first admissions to the Harrisburg State Hospital during a period of five years. All but four patients were more than 40 years of age. A distinction is made between bromide intoxication and delirium. Intoxication is said to exist when the concentration of bromide in the serum is 150 or more mg. of sodium bromide per hundred cubic centimeters. The most convenient method of determination is the Walter-Hauptmann test. With a given degree of intoxication, the occurrence of delirium is assumed to depend on the resistance of the patient. Resistance here means the stability of the highest cerebral centers—their ability to function normally in spite of the paralytic or depressant action of the poison. In the thirty-four cases, bromide delirium was about two and one-half times as common in women as in men. Delirium is a condition marked by dulness, drowsiness, restlessness, thinking difficulty, disorientation, mood disturbances (usually fear), delusions, hallucinations and illusions. Disorientation is essential to the picture; the others may or may not be present—at least, they may or may not be demonstrable. Subjective visual disturbances occurred in many cases and disturbances in equilibrium sense were frequent. After bromides are discontinued, the length of time required for the delirium to disappear varies in most cases from two to six weeks. In a diagnosis of bromide delirium the patient must have a bromide intoxication, the delirium must have begun after the intoxication was already under way and the delirium must disappear within a short time—usually a few weeks, rarely more than two months—after the discontinuance of the drug. Even though a patient has both delirium and bromide intoxication, the latter is not always the sole cause of the former, since there may be additional causes, such as intoxication with other drugs, chronic alcoholism, and metabolic and febrile diseases. In the treatment of bromide delirium the patient should be put to bed immediately and kept there till the delirium is over. If the patient is unduly restless he should be given continuous baths, if available. If sleep is poor, hypnotics should be given, but with great caution. Fluids should be forced moderately. The diet should be soft. Bromides should be discontinued at once. Sodium chloride should be given, provided there is no nephritis. Spinal drainage may be performed to relieve a possible increased intracranial pressure. As in any psychosis, the patient should be watched and the possibility of suicide guarded against.

**Historiography.**—Lamarque outlines a new method to obtain roentgenograms of microscopic sections by the use of very soft x-rays. It is carried out in a vacuum. Special photographic emulsions are utilized which allow greater enlargements. The images obtained, which are examined micro-

an interval of three years. In another patient, whose history is reported, the author administered the prehypophyseal extract subcutaneously as well as by mouth. Moreover, thyroid was given intermittently. The patient gained rapidly in weight, the menstrual flow returned and within a few weeks her general condition had changed completely. The author ascribes the more rapid improvement in this patient to the more intensive treatment. The administration of other than prehypophyseal extracts in hypophyseal insufficiency is indicated only in the extremely severe and prolonged cases of prehypophyseal insufficiency, in which thyroid, adrenals and gonads have become severely involved. Endocrine treatment by means of implantation of animal prehypophyses is indicated only if an activating effect is desired and if the oral or parenteral administration of an extract of the entire prehypophysis does not produce the desired effect.

**Artificial Pneumothorax in Pneumonia.**—Daniels observed a case of pneumonia in a boy, aged 16. An artificial pneumothorax was induced on the third day on account of severe pain. The author discusses pneumonia in general, emphasizing that the pneumothorax therapy exerts its influence only on the pains. He points out that under certain conditions this therapy might be harmful; for instance, in case of severe impairment of the myocardium or in case the other side becomes involved later. Moreover, the displacement of the mediastinum has to be watched for. The author thinks that in pneumonia artificial pneumothorax is justified only if severe pleural pains have to be relieved and even then only in exceptional cases. He does not think that this intervention promises more for the future.

**Alcohol Injections in Treatment of Pulmonary Abscesses.**—After reviewing the literature on this method of treatment, Magnus-Alsleben and his associates report six cases of pulmonary abscess in which they resorted to alcohol injections. A 33 per cent solution of alcohol in distilled water was administered intravenously in quantities of from 75 to 200 cc. at intervals of from four to five days. The total number of injections varied between four and seven. Five of the patients were cured. The authors gained the impression that the alcohol injections exerted a favorable influence on the clinical course, for the temperatures as well as the quantities of sputum decreased following the alcohol injections. In several of the cases a noticeable improvement concurred with the injections after other remedies had been employed for weeks without success.

**Behavior of Curves of Alimentary Glycemia in Pregnancy.**—Addessi studied the behavior of the curve of glycemia in pregnancy after administration of different amounts of dextrose, according to Labbe, Bufano and Faber's tests. The glycemia of normal pregnant women with a fasting stomach is under normal figures or else there is hypoglycemia. The curves of induced hyperglycemia given by the different tests were in agreement. The author concludes that normal pregnancy does not modify the curves of induced hyperglycemia, which show the same characteristics that they have in conditions other than pregnancy. Only during the seventh and eighth months of pregnancy have the curves a slight and transient deviation toward a paradiabetic type, which is due to liver disturbances of fixation of dextrose and also to a lowering of the renal threshold of permeability to dextrose. The renal threshold is not so low as to result in the production of glycosuria, but the stimulation of induced hyperglycemia produces it. The author considers the seventh and eighth months of pregnancy a pathologic period during which the

balance of the mechanism which regulates glycemia in pregnancy is transiently ruptured. By the ninth month of pregnancy the functions controlling glycemia are again normal.

### Minerva Medica, Turin

2: 517-536 (Dec. 1) 1936

\*Action of Histamine on Tuberculous Foci of Lung: Roentgen Study. G. Luzzatto-Fegiz.—p. 524.

Relations Between Erythema Nodosum and Tuberculosis. E. Massobrio and U. Demichelis.—p. 529.

**Action of Histamine on Tuberculous Foci of Lung.**—Luzzatto-Fegiz reported in a previous article a harmless method for auscultation of foci of pulmonary tuberculosis which otherwise are silent. It consists in the administration of a subcutaneous injection of 1 cc. of a 1:1,000 histamine solution. The alterations of respiration, murmurs and râles that are characteristic signs heard by auscultation in pulmonary tuberculosis appear shortly after administration of the injection in four out of every five patients suffering from pulmonary tuberculosis. The injection fails to induce these signs in normal persons. The author made serial roentgenograms at intervals of a few minutes in order to study the anatomic and functional changes induced by the histamine injection in the tuberculous lung. The roentgenograms, compared with those taken in the same position immediately before administration of histamine, showed a clearer and more transparent pulmonary parenchyma around the tuberculous foci, darker tuberculous foci with more definite contours, darker images of the ulcerations of a bread crumb type, constriction of the lumen of the bronchi (except those which were rigid from a process of chronic peribronchitis) and darker and thicker shadows of the blood vessels, especially those near the hilus. If the parenchymal lesions were in an advanced stage, however, the shadows given by the tuberculous foci overshadowed those given by the vessels. According to the author the increased transparency of the lung parenchyma is due to emphysema from spasm of the bronchi. The clear parenchyma, as a field, produces by contrast a good showing of the shadows given by the pulmonary foci and blood vessels. The clear visualization of the ulcerations of the bread crumb types is due to spasm of the arterioles. The anatomic and functional changes induced by histamine in the tuberculous lung, as verified by the author, prove that the roentgen phenomena have as a common producing factor the bronchial spasm induced by histamine. His results prove also the exactness of his opinion as to the mechanism of production of the auscultatory signs by the histamine test. According to the author there is a condition of bronchial stenosis in pulmonary tuberculosis with consequent retention of air in the alveoli which results in the spontaneous production of murmurs and râles at the site of inflammation and edema at the tuberculous foci. When the bronchial spasm is latent, the murmurs and râles fail to be produced. Histamine, which cannot produce bronchial spasm in the normal respiratory tract, changes latent bronchial spasm into actual spasm with consequent development of murmurs and râles, which are audible at the tuberculous foci.

Amyoplasia Congenita Associated with Mongolism. L. C. Cook.—p. 261.

**Banti's Syndrome in Childhood.**—Martin reports four cases showing Banti's syndrome, in three of which the Wassermann reaction was negative and the fragility of red cells, bleeding time and coagulation time were normal. The fourth case exhibited the clinical features of Banti's ascitic stage. The few small palpable glands alone were atypical; the cervical ones were attributed to carious teeth. The absence of a definite leukopenia at such an apparently late stage of Banti's disease in addition to the long history of jaundice was, however, a warning that the case was not entirely typical. The Wassermann reaction was a weak positive. Banti's disease is said to be rare in children. The diagnosis of Banti's disease is seldom made before one of the major symptoms, such as hematemesis or grave anemia, has occurred, although examination of a child with a vague epigastric pain or swelling of the abdomen may reveal an enlarged spleen and a palpable liver. All conditions associated with splenomegaly in childhood must be excluded, and it must be remembered that the hematopoietic system of a child is unstable and reacts violently to stimuli which would have little or no effect on an adult. The reaction may take the form of splenomegaly, hepatomegaly, enlargement of lymphatic glands and varying degrees of anemia—such as occurs typically in von Jaksch's syndrome in response to stimuli like iron deficiency, rickets and syphilis or other infections. The two most important conditions to be excluded before diagnosing Banti's disease are syphilis and acholuric jaundice. Syphilis may exactly simulate Banti's disease, as it did in the author's fourth case, and hepatomegaly may accompany splenomegaly in acholuric jaundice; hence the Wassermann reaction and fragility of red cells are essential investigations. Small doses of iron, as a therapeutic test, may help to exclude an iron deficiency anemia, but massive doses should not be given in view of Davidson's success in the treatment of Banti's disease by such doses of iron. The term Banti's disease should be confined to those cases showing splenomegaly and secondary anemia, with or without hemorrhages and hepatic cirrhosis, but in which no known etiologic factor is present. Similarly splenic anemia should be applied to cases showing Banti's syndrome when some vascular disorder or specific infection can be recognized during life. The finding of portal or splenic thrombophlebitis at necropsy in a case of Banti's disease should not nullify the diagnosis made during life, until further work has shown whether such vascular abnormality is a cause or sequel.

**The Blood Sugar in Convulsions in Childhood.**—In view of the confusion of opinion regarding the rôle of hypoglycemia in the etiology of convulsions in childhood, Maclean performed blood sugar estimations in fifty children admitted to the hospital because of convulsions and made an attempt to follow the changes occurring in the blood sugar level from the beginning of a convulsion until some hours after it had ceased. The blood sugar was estimated at frequent intervals, often hourly. High blood sugar values occurred most frequently in the first three hours after the convulsion and often persisted into the fourth to the twelfth hour. There are as a general rule two phases, a state of hyperglycemia followed by one of hypoglycemia. A blood sugar level of more than 180 mg. was taken as indicating hyperglycemia and one of less than 60 mg. as hypoglycemia. Except in cases of true hyperinsulinism it would appear that hypoglycemia plays no part in the causation of the convulsions of childhood and that the upset in carbohydrate metabolism is the result and not the cause of the convulsions.

**The Problem of Anuria.**—Neither of the two cases reported by Cubitt can be certainly put in the class of reflex anuria, but they both present unusual features. In the first case the obstructed kidney showed a dense shadow in the roentgenogram, presumably because of its congestion. The contralateral kidney was probably functionless. The ureteral calculus which was subsequently passed did not show in the roentgenogram. The symptoms of anuria were early in their appearance. Restoration of the flow of urine, probably due to the passage into the bladder of the stone blocking the ureter of a solitary functional kidney, followed the administration of intravenous saline solution. In the second case complete anuria followed nephropexy; both kidneys had been proved previously to be functioning perfectly. The cause was probably partly obstructive and partly infective. The symptoms were unusually early and severe. Restoration of the flow of urine and relief of symptoms followed a combination of intravenous dextrose, spinal anesthetic and bilateral ureteral catheterization. Spinal anesthesia is worthy of trial in cases of reflex anuria. This applies whatever its etiology, since the afferent path at least must be a nervous one. The experimental work done by physiologists in the last few years dealing with the blood supply of the kidneys, its response to humoral and nervous influences and the effect on the secretion of urine of these changes in blood supply and of changes in the urine pressure has an important bearing on the problem of anuria. Winton's conception of intrarenal pressure in particular is full of possibilities and requires further work. The author's tentative explanation of reflex anuria embodies the following possible sequence of events: spasm of one ureter in response to impaction of a stone sets up afferent nervous impulses which, either by direct reflex action or by release of some endocrine substance, cause vascular changes in the other kidney, an alteration in capillary permeability and an exudation of fluid into the renal parenchyma; the raised intrarenal pressure obstructs the tubules and raises the urine pressure opposing filtration; at the same time it causes partial obstruction to the venous outflow so that the kidney is congested with blood. Contributory factors may be (1) lowering of general blood pressure and (2) abnormal leak of urine back through the tubules into the blood stream, as a result of increased urine pressure.

**Multiple Arthritis in Presumably Tuberculous Subjects.**—Collins and Cameron present twelve cases that include a variety of arthritic manifestations occurring in tuberculous subjects. Every investigation and observation that they have been able to make has led them to the conclusion that, with the exception of three, none of these patients suffered from a

detailed descriptions of two technics, the first to be used for urines that give a positive Griess reaction and the second for urines with a negative Griess reaction. In the conclusion she emphasizes that in order to obtain satisfactory results it is necessary to follow the directions exactly. With her improved technic she was able to reduce the erroneous reactions to less than 4 per cent.

**Demonstration of Active Principle by Ultrafiltration Methods.**—Anselmino and Hoffmann point out that in 1931 they demonstrated, with the aid of an ultrafiltration method, an antidiuretic and a vasopressor substance in the blood of patients with eclampsia or with nephropathy and proved that this antidiuretic substance is identical with the antidiuretic component of the posterior lobe of the hypophysis. Since the effects of these substances corresponded to the clinical symptoms of the pregnancy toxoses, they ascribed the latter to an incretory disturbance in which a pathologically increased formation of the active principle of the posterior hypophysis played the most important part. Their observations were reinvestigated by others, some of whom obtained contradictory results, in that they were unable to identify the antidiuretic substances in the blood of eclamptic patients with the antidiuretic component of the posterior lobe of the hypophysis. The authors show that this inability of the other investigators to identify the two substances is due to the fact that they employed a different ultrafiltration method. Instead of using the glacial acetic acid collodion membrane employed by the authors, they used an alcohol-ether-collodion membrane of several layers, which was put through a drying process. The authors state that the drying process makes the membrane impermeable for the principle of the posterior lobe of the hypophysis. They further describe their own technic and then report experiments. In one group of experiments they extracted the posterior pituitary principle that had been added to serums in vitro and in a second group they extracted posterior pituitary principle from the blood of dogs that had been given injections of the extract.

**Results of Transplantation of Hypophyseal Tissue.**—Kylin was induced to try the transplantation of hypophyseal tissues from calves to patients with hypophyseal cachexia (Simmonds' disease) by von Bergmann's report on three cases. Kylin employed the method in twenty-four patients, twenty-three of whom had Simmonds' disease. Twelve of these were completely cured and six were greatly improved, but since the elapsed time is still rather short a final evaluation is impossible as yet. Two patients died; one immediately after the operation and the other three months later. In three others the operation is of recent date. The first signs of improvement were usually observed after one or two months, but the increase in weight usually did not start until two or three months had elapsed. The hypophyseal transplantation proved valuable also in a youth, aged 19, who had adipogenital dystrophy.

\*Observations on Mild Attacks of Influenza During Puerperium. E. Schneider.—p. 1728.

**Mild Attacks of Influenza During Puerperium.**—Schneider states that the thirty-seven cases of influenza he observed among 1,472 puerperal women were mild and that the recovery

was more rapid than is ordinarily the case in influenza. The unusually short duration of the influenza even in patients with rather high fever, severe impairment of the general condition, reddishness and painfulness of the pharynx and conjunctivae and painful cough is ascribed by the author to the fact that treatment was begun immediately after the first signs of influenza became noticeable. The women were kept in bed. They were given large doses of salicylate and usually also aminopyrine. In a few instances cardiac remedies were given. The cough was relieved with codeine syrup, and generous amounts of fluid were given. The lactation process was not impaired and the women continued to nurse their infants. However, in order to protect the infants against infection by droplets a cloth was placed around the woman's mouth and nose during nursing. In discussing the differential diagnosis of influenza during the puerperium the author says that, if the genitalia are free from changes, if there are no signs of cystitis, pyelitis, typhoid, articular rheumatism or recurrent tuberculosis and if the pharynx is hyperemic but without signs of angina, influenza may be considered a possible cause of the febrile temperature, the dryness of the oral and pharyngeal mucous membranes, the involvement of the conjunctivae and the general indisposition.

\*Influence of Roentgen Rays on Cholesterol Content of Blood and Serum of Women Without and With Carcinoma or Sarcoma. P. H. Schumacher and Rusch.—p. 532.

**Course of Radium Erythema.**—Zuhelle studied the reactivity of the skin to radium rays in experiments on himself. He applied the radium rays to several areas on his left arm by means of 10 mg. of radium element, which was filtered with 0.5 mm. of brass. The irradiation usually lasted about four hours. Several hours after the irradiation a follicular erythema appeared. However, this early erythema disappeared in from three to four days. Then followed a period of latency. After five weeks a rather severe erythema with swelling developed, which was preceded by a speckled reddishness. About six weeks after the radium irradiation a blister developed on the erythema, which burst about a week later. After that the inflammation subsided rapidly, forming a yellowish brown adherent crust. Later the crust came off and a slightly depressed scale-covered area remained, the depression still being noticeable after a year. The course of the reaction was the same in eight different tests, which the author made on himself. In order to be able to make histologic studies, he decided to make animal experiments. He applied radium rays to the comb and wattles of cocks. Contrary to expectation he found that these organs react to radium rays with pallor. The histologic explanation of the pallor lies in a thickening or swelling of the collagen with constriction of the vessels, and the blister formation is due to a blister-like detachment of necrotic epidermis without exudation. He emphasizes that the highly vascular comb and wattles are especially suitable for disclosing changes in the collagen, because of the loose structure of the connective tissue. It was found that the connective tissue is involved in the reaction to irradiation by way of colloidal chemistry rather than through the action of the cells. Thus the author's investigations corroborate the observations of other investigators on the radiosensitivity of the collagenic fiber and indicate that in irradiation the chemical changes in the intercellular substance are more important than cellular changes.

**Borderline Rays in Treatment of Naevus Flammeus.**—Kalz states that he employed borderline rays in the treatment of forty-nine cases of a naevus flammeus. He usually applied

whether the appendix is to be seen or not. The position of the transverse colon is marked. No further observations as to abnormalities are made on the colon except in special cases. This terminates the examination. If special observations are to be made on the colon, they are carried out by means of the barium enema. Of 752 roentgen examinations of the gastro-intestinal tract carried out in St. Vincent's Hospital, the diagnosis was correct in all except four cases.

**Passive Anaphylaxis Following Immediate Injection of Antigen After Antiserum.**—The experiments of Dean and his collaborators show that an intravenous injection of antigen immediately after an intravenous injection of antiserum in the guinea-pig had the following results: 1. When acute shock and death took place within five minutes, the signs and postmortem appearances were indistinguishable from acute anaphylactic shock as typically seen in the guinea-pig. Some control animals injected only with antiserum died in a way similar to those which received both antiserum and antigen. 2. When delayed shock and death occurred some hours later, the postmortem appearances were those of gastro-intestinal congestion and hemorrhage resembling the changes seen in dogs dying of anaphylactic shock. Such changes were never seen in the control animals. 3. Practically all the animals which recovered had symptoms of respiratory embarrassment immediately following the injections of antiserum and antigen and many had later symptoms of abdominal shock. The animals that were given an injection of antiserum had symptoms only rarely and never abdominal symptoms. It is necessary to test the antisera used by control inoculation, since some antisera are toxic. Passive anaphylaxis can be produced by the intravenous injection of antigen immediately following that of antiserum, but it is easier to produce it by allowing an interval between the two injections.

**Rheumatic Fever.**—Coburn points out that in most individuals hemolytic streptococcal pharyngitis is followed by uncomplicated recovery. However, a small minority develop rheumatic fever shortly after convalescence from this type of infection. The author attempts to interpret the relationship of the immune response to the development of the rheumatic

process. The data consist of observations on the serologic events immediately following hemolytic streptococcal pharyngitis. Variations in the clinical character of the attack show a close parallel to the types of antistreptolysin curves developed. The immune responses of the rheumatic individual differ from the normal in that they are delayed. If this should prove to be true in the light of more extensive data on normal responses, it must be assumed that the rheumatic subject who develops an attack handles the products of the hemolytic streptococcus in a peculiar way. Such a concept harmonizes well with the prolonged antigenicity of this organism during rheumatic attacks as evidenced by the persistence of high antistreptolysin titer levels for months after infection. In addition to the apparent delay in the immune response of the rheumatic subject, there may also be a delay in the final elimination of hemolytic streptococcus products from the body. These observations suggest the hypothesis that the rheumatic state is characterized by an abnormal method of disposing of hemolytic streptococcus products. The mechanism whereby such an abnormal immune response may induce disease is unknown. Further information on the nature of this abnormality may make possible an experimental approach to the mechanism.

### Mandelic Acid in Treatment of Pyelitis in Childhood.

—Newns and Wilson used mandelic acid in the treatment of thirty-six cases of pyelitis in children less than 12 years of age. There were twenty-four cases of acute pyelitis, ten cases were chronic or relapsing and in two albuminuria and casts were present, owing probably to pyelonephritis. Ten of the children had been treated unsuccessfully with potassium citrate before the administration of mandelic acid. Mandelic acid with sodium bicarbonate was used in most of the cases and was given in doses of from 15 to 30 grains (1 to 2 Gm.) four times a day, according to the age of the child. In all but three patients the urine was rendered sterile, often within a week of the beginning of treatment. The unsuccessful cases included a *Bacillus mucosus-capsulatus* pyelitis and a *Bacillus proteus*-pyelitis complicating pink disease. Little difficulty was experienced in reducing the  $pH$  to the optimal level of 5.3. Side effects were noted in two cases: in one diarrhea developed, necessitating temporary cessation of treatment; the other child had some vomiting. No harmful effects on the kidneys were observed. So far, of the thirty-six patients treated, nine have had relapses; three of these have had a second course of treatment which has produced a sterile urine. Of the nine relapses three were in patients with abnormalities of the urinary tract and two in infections with an organism other than *Bacillus coli*. Such infections do not yield so readily to mandelic acid therapy. Four cases are thus left for which no reason for relapse can be given.

persons. The onset of the disease exhibits less pronounced pain, and temperature reaction, nausea and vomiting are noted less frequently, the typical local tenderness at McBurney's point may be absent and the tenderness frequently extends beyond the right lower abdominal quadrant. Atypical complaints and historical data further obscure the picture. The leukocyte count is relatively lower than anticipated and occasionally leukopenia may exist. The pathologic alterations in the appendix are more pronounced and the percentage of perforations is high. The course of the disease is characterized by grave complications and a high mortality rate. There is a frequent lack of relationship between the clinical symptoms and the pathologic observations. Profound pathologic alterations may exist in patients with trivial complaints and apparently insignificant objective signs. The high mortality index in the old depends principally on the rapid development of pathologic alterations. On the other hand, patients operated on early give a mortality rate not much higher than that of the younger groups.

**Surgery of Cancer of the Colon.**—Turovets considers the early diagnosis of cancer and its precancerous stage the most important factor in the treatment of colonic cancer. Early diagnosis will be possible only when the practicing physician will resort to clinical, laboratory and roentgenologic methods of examination. The early diagnosis of malignant neoplasm of the large intestine is made difficult by the fact that not infrequently it may run an asymptomatic course. The so-called general abdominal complaints of the middle aged may be its first symptoms and therefore call for a careful examination, including roentgenography. In cases difficult to diagnose, exploratory laparotomy is indicated. The author includes regional chronic colitis among the inflammatory and degenerative processes that may serve as a soil for the development of cancer of the colon. Polyposis, itself the result of various inflammatory processes, merits particular attention as a precancerous condition. The author stresses early operation and the widening of indications for a one-stage resection even in the presence of acute obstruction. Early resection gives a high percentage of permanent recoveries.

### Circumscribed Cranial Osteoporosis with Psychosis.

Van der Heide relates the clinical history of a woman, aged 48, who was hospitalized on account of a paranoid-hallucinatory condition. Because it seemed probable that the psychosis developed on an organic basis, a roentgenogram of the skull was made and revealed pathologic changes in the bones finally identified as circumscribed cranial osteoporosis, which was first described by Schüller. The other portions of the skeleton were normal except for an irregular and rather coarse structure of the bone in the right ilium, which suggested Paget's disease. An exploratory excision from the temporal bone revealed almost normal bone. Following a review of the literature on circumscribed cranial osteoporosis, the author discusses the differential diagnosis with regard to Schüller-Christian's disease and to osteitis fibrosa cystica generalisata (von Recklinghausen). Finally he cites factors indicating a connection between circumscribed cranial osteoporosis and Paget's disease.

### Finska Läkaresällskapets Handlingar, Helsingfors

79: 839-931 (Oct.) 1936

Experiences with Finland's Red Cross Ambulance in Abyssinia. R. Faltin.—p. 848.

\*So-Called Myeloid Reaction. G. Tötterman.—p. 850.

\*Changes in Central Nervous System in Leukosis. R. Gordin.—p. 889.

**So-Called Myeloid Reaction.**—Tötterman's first case of so-called myeloid reaction occurred in a woman, aged 40, in connection with a subchronic polyarthritis. The highest num-

ber of white blood corpuscles was 21,200, with more than 40 per cent neutrophil myelocytes and metamyelocytes; normoblasts were abundant. The results of a sternal puncture testified definitely against leukemia. During almost two years' observation, no aggravation in the patient's condition has appeared. In the second instance, a man aged 31, with bothrioccephalus anemia, there was a large number of immature leukocytes in the blood after pneumonia, with a total of 28,400 white blood corpuscles and more than 40 per cent myelocytes and metamyelocytes. After treatment of the bothrioccephalus anemia the blood picture rapidly became normal.

### Changes in Central Nervous System in Leukosis.

Gordin says that these changes in leukosis may depend (1) on hemorrhages in connection with the hemorrhagic diathesis, (2) on leukemic changes in the blood vessels and (3) on infiltration with specific leukemic tissue. The last named changes occurred mainly in acute leukoses (including chloroleukemia) and especially in lymphadenoses. Specific leukemic changes in the meninges and the nerves of the brain or the spinal roots are not uncommon. The most frequent disturbance of the spinal cord is a compression syndrome, caused by epidural leukemic tumor masses. In a patient presenting symptoms of acute ascending myelitis, leading in the course of two months to tetraplegia, paralysis of respiration and death, the lymph nodes were slightly enlarged and there were tumor-like nodules in the skin; a hemorrhagic diathesis and specific changes in the blood picture were absent. The epidural tumor of the spinal cord revealed at necropsy was made up of lymphoid tissue with lymphoblast and lymphocyte-like cells, also fibrocytes and macrophages. Similar tissue was found in the kidneys, in the lymph nodes and cutaneous tumors as well as in the stomach, where ulcerations surrounded by lymphoid tissue had developed. In the upper dorsal region the spinal tumor had caused myelomalacia. Hydromyelocele was also seen, with fenestration and degeneration of strands and acute changes in the ganglion cells. The author concludes that the tumors in the different organs were coordinated in their origin and of benign type, and he considers the case one of atypical leukosis, most nearly resembling a lymphadenosis. In a second case described there were simultaneous leukosis and a malignant brain tumor (glioma of spongioblastoma type).

Investigations on Content of Aminolipoid (Cephalin) in Plasma in Psychoses. L. Laursen.—p. 1227.

**Preoperative Electrocardiography and Roentgen Examination of Heart.**—Foged and Geill made electrocardiographic and roentgen examinations of the heart in 428 cases in which an important surgical intervention was indicated. In 253 of the 353 patients operated on in whom clinical examination failed to reveal any pathologic changes in the heart, the results of electrocardiography and roentgen examination agreed with the clinical results; the operative mortality due to heart weakness was 1.1 per cent. In the remaining 100, in whom electrocardiogram or roentgenogram, or both, disclosed abnormality in the heart, the operative mortality from impairment of the heart was 11.8 per cent. It seems to the authors justifiable to accept the outcome of these examinations as a factor in considering the operative risk, when the indication is not imperative. In certain cases the result of the examinations contraindicates the operation; in others it helps to decide the extent of the intervention. Myocardial degeneration and coronary disturbance undoubtedly constitute a grave contraindication for important surgical interventions. The operative prognosis in the various forms of cardiac disorder must be more closely determined by continued investigations in greater numbers of patients.

**Gastric Atrophy and Intermediate Malignant Anemia.**

—Boulín and his collaborators report a case of intermediate malignant anemia with gastric atrophy from the anatomopathologic point of view. The patient was a man, aged 82, who complained of continuous abdominal pain, affecting chiefly the right hypochondrium and the periumbilical region. The first date of appearance of these symptoms was almost thirty years prior to this hospital admission. For several months, however, the patient complained of generalized asthenia and loss of weight. The tongue showed the classic glossitis. There was tympany of the cecal region, but no abdominal tenderness. The achilles reflexes were abolished and the pulse was rapid but there were no other important physical signs. Test meals of the stomach revealed no free acidity. The blood showed megalocytic hyperchromic anemia, with 1,850,000 red cells and a hemoglobin of 45 per cent. In spite of the institution of liver therapy the patient died shortly from intercurrent infection. Examination of the organs of the body failed to reveal any abnormality other than that of the gastric mucosa, which was characterized by marked atrophy. The vascular network was visible because of the relative transparency of the mucosa. Microscopically the atrophy involved the submucosa and mucosa more than the muscular layer. The fundus glands were modified to resemble the pyloric glands. In places the mucosa was reduced to a band of sclerous tissue. Infiltration of lymphocytes and plasmocytes involved the muscular layers. It was almost impossible to find the nerve plexuses, since they were destroyed by sclerosis. These characteristics correspond to the description of simple atrophic gastritis, except for the vascular dilatations, which were similar to those observed in linitis. Furthermore, this anatomopathologic description accordingly reveals the endoscopic characteristics of atrophic gastritis, with a well developed atrophic process and an advanced vascular dilatation.

Humoral Factor in Measles Anergy. V. de Lavergne and H. Accoyer.—p. 1420.

**Erythremia Improved by Phenylhydrazine Hydrochloride.**—Béthoux and Marcoulidès report the case of a patient with essential erythremia, treated at first by teleoroentgen therapy, without apparent success. This was followed by treatment with phenylhydrazine, which led to rapid improvement from both the hematologic and the clinical standpoint. The dosage of phenylhydrazine hydrochloride was 0.05 Gm. for four days, 0.1 Gm. for four days and 0.15 Gm. for three days. This observation shows that, in spite of a total irradiation involving relatively strong doses, the erythrocytes remained at a relatively high level, and that from a clinical standpoint irradiation seemed even to be harmful to the patient. Headaches in particular seemed to be exaggerated. Furthermore, if the difficulty of application of teleoroentgen therapy is considered, the comparative simplicity of chemotherapy tends to lead primary choice toward the latter.

- Röntgenologic Study of Pulmonary Mechanism in Latero-Inclined Position. Lowys, Marinot and Marlin.—p. 890.  
\*Mechanism of In Vitro Leukocytic Reactions in Presence of Tuberculin. R. Kirsch.—p. 910.

**In Vitro Leukocytic Reactions to Tuberculin.**—Kirsch employs the following method for studying the reaction of leukocytes to tuberculin: The blood, after centrifugation and

removal of the larger portion of the citrated plasma, is washed several times in physiologic solution of sodium chloride. The leukocytes remaining in contact with the red blood cells are placed in an incubator at 37 C. and incubated with the diluted old tuberculin of Koch and with fresh serum from the same individual. After incubation for twenty minutes or more the smears are fixed, stained and examined. The changes in the polymorphonuclear cells and large monocytes are noteworthy. Eosinophils and lymphocytes do not appear to be modified. The polymorphonuclear neutrophils usually show chromatic changes and vacuolization of the protoplasm. The large mononuclears are less affected but frequently show protoplasmic vacuolization. They agglutinate with each other and with the polymorphonuclear cells, and their borders become indistinct. When physiologic solution of sodium chloride is used instead of homologous serum, the changes in the leukocytes are minimal. In a number of other experiments the author used substances other than the serum of the individual whose blood was to be tested. Thus guinea-pig serum, calcium chloride and sodium citrate were employed in some tests. Glycerinated peptone bouillon, peptones and proteins of egg white were also used. The combined results of these experiments lead to the conclusion that tuberculin, concentrated glycerinated peptone bouillon, peptones and egg white proteins exert a rapid and intense toxic action on the washed leukocytes of allergic origin in the presence of fresh serum. These changes are observed in a distinctly modified fashion in the presence of heated serum. The polymorphonuclear neutrophils and the large monocytes fix the toxic elements of these solutions, even in the absence of serum, but they are not themselves changed except in the presence of fresh serum. Calcium chloride and sodium citrate prevent the action of fresh serum, probably by the inhibition of the complement of the serum. Finally, tuberculin and the peptones toxify fresh homologous or heterologous serum, and this toxicity does not disappear by heating at 57 C.

**Hormone Treatment of Simmonds' Disease.**—Schüpbach points out that Simmonds' disease is now identified with prehypophyseal insufficiency, because the original term hypophyseal cachexia, is too restrictive. The abolishment of the prehypophyseal function may be caused by anatomic processes, such as tumors, inflammations, traumas and syphilitic lesions, but the disturbance may also be of a purely functional nature. This last group includes many of the milder forms, such as the exhaustive states in constitutional asthenia. In this connection the author mentions also the persons who are always weak and tired and who have low arterial pressure, a tendency to fainting, poor appetite, constipation and so on. The physical weakness is frequently accompanied by similar psychic reactions. In discussing the treatment of prehypophyseal insufficiency, the author gives his attention to cases in which a functional rather than an anatomic disorder of the prehypophysis is the cause. He emphasizes that, since the disorder is caused by an insufficiency of the entire prehypophysis and not merely by a deficiency of some of its numerous hormones, the treatment should employ those preparations which most nearly exert the effect of the entire prehypophysis. He reports the histories of several patients in whom he produced good results with a prehypophyseal extract. The first case concerns a woman, aged 38, who received three times daily two tablets of a prehypophyseal extract. This oral therapy was continued for a year. The patient gained 25 Kg. in weight and menstruation returned after

more ideal environment, and we feel certain that, with more adequate physical equipment, more nursing help and increased latitude as to available medicaments, both our mortality rate and the average stay of such cases in the hospital could be further diminished.

We shall not go into the pathology, actual or conjectural, of delirium tremens. In considering this disease therapeutically, however, it should be remembered that in delirium tremens one is dealing with a condition characterized by physical intoxication and by mental and physical excitement. The therapy should have as its aims the speedy elimination of whatever toxins are present and the protection of those organs and physical functions which might be damaged by the intoxication, together with an amelioration of the excitement and the protection of the patient against the possible untoward results of abnormally great activity. The treatment, then, may be discussed under five main heads:

1. The safeguarding of the patient against injury to himself or to others.
2. The prevention of exhaustion.
3. The promotion of elimination, both gastro-enteric and urinary.
4. The decrease of intracranial edema and pressure.
5. The promotion of adequate nutrition.

#### SAFEGUARDING THE PATIENT

Any one who has had the opportunity to spend some time with an active delirium tremens patient can readily understand how the patient's apprehension, hallucinations and delusions might cause him to injure himself, perhaps fatally, in an attempt to escape the creations of a delirious brain, or how he might injure others in trying to defend himself against his imagined torturers. It is practically impossible, in most instances, to provide constant observation and protection for such a patient outside of an adequately equipped and staffed hospital. The physician in charge of such a case would be wise, both for the sake of the patient and in order to protect his own interests, to insist on hospitalization. Not long ago, in one of the surgical wards of the Cincinnati General Hospital, a fortunately robust nurse managed to grasp and hold on to the ankles of a patient in whom delirium tremens had developed after admission and who had started a dive through an open third story window. Incidents of this sort are sufficiently common to justify exercising the utmost in anticipatory caution in the handling of these cases.

#### PREVENTION OF EXHAUSTION

The phase of the treatment having to do with the prevention of exhaustion may be subdivided into two lanes of approach, both of considerable importance. Of the sixteen deaths occurring in this series of cases, nine presented serious complications—one suppurative parotitis and bronchopneumonia, one severe gastric hemorrhage and lobar pneumonia, two heat stroke, three lobar pneumonia, one bronchopneumonia, one severe stab wounds of the chest and abdomen—complications which might of themselves, without the alcoholic factor, have caused the deaths. The other seven cases were characterized clinically chiefly by signs of cerebral inflammation and by heart failure. We regret that of these seven uncomplicated cases only four autopsies were obtained. In each of these four cases, however, one of the most prominent observations was that of a pronounced toxic myocarditis. It is our feel-

ing that one of the main causes of death in uncomplicated delirium tremens is heart failure, both of itself and indirectly because of the increase in toxicity and impairment of organ function generally that is incident to an inadequate circulation. It is not difficult to understand how this failure may occur when one considers the actual intoxication of cardiac musculature that is present and the additional strain that is placed on an already intoxicated heart by the patient's excessive activity. In an attempt to anticipate the occurrence of such failure we have inculcated into our routine treatment complete digitalization of the patient. It is our custom to begin digitalization of these patients as soon as the diagnosis is made, to digitalize them completely in from thirty-six to forty-eight hours, and then to administer a maintenance dose daily until recovery from the delirium tremens has been accomplished. In addition, the hypodermic caffeine and intravenous dextrose that we give has as one of its purposes the reenforcement of circulatory efficiency. Among the other drugs suggested by some clinicians for circulatory support are strychnine, camphor, strophanthus and ergot. We have had no experience with these medications in delirium tremens, so that we are not prepared to comment on their value. We feel quite strongly, however, concerning the advisability of cardiac medication, and it is our belief that this part of our treatment has played a large part in the diminution of our death rate. To give digitalis to these patients only after signs of heart failure have become manifest has proved, in our experience, of little avail. When the heart begins to fail in delirium tremens, the downhill course is usually rapid and the patient is overwhelmed to the stage of being unable to react favorably to medication of any sort.

The second item under the prevention of exhaustion is sedation. It is well known that if the delirium tremens patient can relax into sleep for six or seven hours the disease is well on its way to being overcome. To obtain this sleep, however, is no simple matter. A search through the literature for recommended sedative measures in delirium tremens elicits a list that rivals the pharmacopeia as to all-inclusiveness, from morphine to hydrotherapy, and from the injection of magnesium sulfate intraspinally to soothing reassurances. One writer recommends the use of a cluster of blue lights in an otherwise dark room. Another would have one take a bucket of tepid water, heavily impregnated with salt, and dash it over the patient. The latter two procedures go back many years. The more recent suggestions as to sedative methods are more specific medically but are so varied that one cannot but conclude that the problem of sedation in delirium tremens is still for the most part unsolved. In general, when choosing a sedative for these patients it is well to remember that one is dealing with individuals who are already intoxicated, whose circulatory efficiency needs to be stimulated rather than depressed, and whose kidney function is fairly frequently impaired to some degree so that elimination of the sedative by way of the urine is not to be relied on to too great an extent. We have found paraldehyde, administered orally or rectally, the most innocuous, the most rapidly eliminated and the most uniformly effective of the sedatives available at the hospital. Despite its unpleasant odor and taste, we have encountered little objection to its ingestion on the part of our patients. The barbiturate group—orally, hypodermically or intramuscularly—in ordi-

fixation of calcium and formation of bone callus. The roentgen examination of the fracture shows a larger and thicker callus in rabbits treated with cholesterol injections than in the controls. The histologic examination of preparations of the fracture shows that the processes of proliferation, disappearance of cartilaginous tissues, transformation of osteoid tissue into bone and internal reconstruction of the medullary canal and of the diaphyseal cylinder are accelerated by cholesterol local treatment. The acceleration of the process of consolidation is more rapid and marked from the tenth to the twentieth day of the treatment than before and after those days. The results of the author's experiments confirm the relations between the local lipid trophism and the fixation of calcium salts. The mechanism by which fixation of calcium salts and healing of the fracture take place is due to local and general modifications of the calcium metabolism by action of the local treatment, and also to local chemical combinations of calcium and phosphorus in presence of cholesterol at the site of the fracture.

**Hypernephroma with Ganglionic Metastases.**—Aguirre and Nino report a case of hypernephroma with generalized metastases of the ganglions in a patient, aged 32. The histologic study of a ganglion of the neck removed for biopsy showed hypernephroma metastasis and the x-ray study of the patient showed the presence of large metastases in the spleen and lungs. The kidneys were enlarged and ptotic. Renal function was normal. The authors conclude that hypernephroma of Grawitz type is frequent. The tumor evolves for some years without any local or general symptoms. The metastases formed develop rapidly, reach a larger size than the original tumor and cause the predominant symptoms of the disease. The visceral and skeletal metastases, which are the earliest and most frequent, are formed through the blood. The malignant infiltration of the renal capsule, with consequent rupture of the structure and rapid destruction of the perirenal tissues, which takes place in the advanced stage of hypernephroma, results in spread of the tumor by contiguity into the neighboring organs, the juxtathoracic ganglions and the regional lymphatics. The development of metastases in the ganglions, especially the peripheral ones, indicates an advanced phase of hypernephroma. It coincides with cachexia. Both conditions are contraindications for any operation.

\*Rare Localization of Neuro-Anemic Syndrome. J. F. Tourreilles and P. C. Vázquez.—p. 1583.  
Treatment of Chancroid by Emetine Hydrochloride. C. Visconti.—p. 1595.

**Neuro-Anemic Syndrome of Unusual Localization.**—Tourreilles and Vázquez say that the neuro-anemic syndrome of pernicious anemia may involve the anterior, lateral and posterior gray columns of the spinal cord, either separately or simultaneously. When the syndrome develops in the posterior column, the lesions may involve the cervical or the lumbosacral segments of the spinal cord, causing nervous symptoms in the upper or lower extremities, or they may involve simultaneously different segments, causing symptoms in both the upper and the lower extremities. The diagnosis of the neuro-anemic syndrome is made by the coexistence of pernicious anemia and sensory and motor disturbances in persons in whom

the Argyll Robertson pupil fails to appear. A differential diagnosis of the nervous symptoms is made with those of hereditary cerebellar ataxia, tabes, amyotrophic lateral sclerosis and nerve syphilis. In making a regional diagnosis the spinal, cerebral and polyneuritic localizations of the nervous lesions have to be considered. When pyramidal symptoms do not appear, it is difficult to differentiate the spinal and polyneuritic location of the nervous lesions. The authors' patient, aged 60, reported for the first time with a syndrome of pernicious anemia, which was controlled by liver treatment. She had three recurrences at intervals of about one year; they occurred whenever the patient stopped the liver treatment. Nervous symptoms at the shoulder and scapular region with consequent muscular atrophy of the arm complicated anemia. Nerve syphilis did not exist. Pyramidal symptoms failed to appear. A diagnosis of neuro-anemic syndrome with nervous lesions of the posterior column of the cervical region was made. It was based on the unilateral character of the nervous lesion and the results of the tests of the cerebrospinal fluid. The results of liver treatment in this case indicate a favorable reaction of those patients to the treatment. The fact calls for verification of statements previously reported in the literature on harmful results of the liver treatment in the neuro-anemic syndrome. The case described by the authors is the first one reported in the literature of neuro-anemic syndrome with lesions in the posterior columns of the cervical region.

\*Treatment of Splenomegalic Conditions. P. Riolo.—p. 1726.  
\*Improved Method of Histidine Reaction for Chemical Pregnancy Diagnosis. Regine Kapeller-Adler.—p. 1728.

**Treatment of Splenomegalic Conditions.**—Riolo followed the suggestion of Ascoli and Diliberto and treated malarial splenomegalies by means of intravenous injections of epinephrine, because the subcutaneous injections did not produce the desired results. He begins with 0.01 mg. (in 1 cc. of sterile water) and increases this dose gradually up to 0.05 or 0.1 mg., depending on the tolerance of the individual patient. The final dose is repeated twenty times until the splenic tumor disappears or is no longer influenced by further injections. Aside from reducing or counteracting the splenic tumor, the intravenous injections of epinephrine also counteract the dyspeptic disturbances that usually accompany the splenic enlargement and the splenic and perisplenic pains of patients with chronic malaria. The epinephrine treatment often results in a reactivation of the malarial infection; however, this does not impair the patient's general condition but only makes an adjuvant quinine cure advisable. Especially noteworthy is the improvement in the blood picture; namely, a considerable increase in the number of erythrocytes. Thus the epinephrine injections are also an effective treatment of the malarial anemia. The intravenous administration of epinephrine is indicated not only in malarial splenomegaly but also in the hemolytic and thrombopenic forms of splenomegaly.

**Histidine Reaction for Chemical Diagnosis of Pregnancy.**—Kapeller-Adler cites the authors who employed her histidine reaction for the diagnosis of pregnancy and shows why some of them obtained unsatisfactory results. To be sure, Stern discovered a source of error in the method. He showed that urines of patients with pregnancy pyelitis which gave a positive Griess reaction for nitrites usually had negative histidine reactions. In order to eliminate the shortcomings of the histidine reaction, Kapeller-Adler made further experiments. She found that urines containing nitrites and histidine will give a positive histidine reaction provided the urine is first treated with tenth-normal potassium permanganate in sulfuric acid solution, which oxidizes the interfering nitrites. She then gives

treated in the past three and a half years this procedure did not cause a serious reaction in a single instance. We would emphasize, however, that the fluid should never be allowed to escape too rapidly.

In addition to spinal fluid drainage, decrease in intracranial congestion is also promoted by the use of hypertonic dextrose given intravenously, by intramuscular hypertonic magnesium sulfate and by hypodermically administered caffeine, the last named having been demonstrated to have a definite diminishing effect on intracranial pressure.<sup>3</sup>

#### PROMOTION OF NUTRITION

It has been suggested in recent years that some of the so-called alcoholic psychoses are not actually due to the alcohol itself but rather to a coincidental malnutrition secondary to the alcoholism. More specifically, a lack of vitamins—principally of the B group—has been blamed, and perhaps with considerable justification. Whether or not this also applies to the acute, brief episode that is delirium tremens is more problematic. Nevertheless, it is true that most individuals suffering from delirium tremens have either neglected their food needs because of lack of appetite for from several days to several weeks or have derived little actual nutritional value from their food because of disordered gastro-enteric systems.<sup>5</sup> Our patients, consequently, have the ability to fight their disease limited by malnutrition. It is necessary, therefore, to take steps to help the patient's nutrition in every way possible. Because of the gastritis that is so often present, it is well to order a soft diet—in some instances a liquid diet. The nourishment should have a high caloric value and, when possible, a high vitamin content. In those cases presenting an especially severe gastritis, lavage is indicated. In this connection it has been our experience that it is usually unnecessary to pass a tube, as the patient will willingly drink from 1 to 2 quarts of a sodium bicarbonate solution and vomit it in order to relieve himself of his gastric distress. It is important to alleviate this distress not only to promote nutrition but to ameliorate the feeling of apprehensiveness and restlessness that is usually a concomitant of a sick stomach.

To recapitulate, and with the addition of a few more details which complete our regimen, our treatment of delirium tremens is as follows:

1. No alcohol is given the patient from the time that he comes under our direction.

2. Absolute bed rest is ordered in an attempt to avoid as far as possible physical strain on the heart and to give the patient the maximum opportunity for sleep.

3. Close observation on the part of the ward personnel is insisted on, so that the patient has a minimal chance to injure himself or others.

4. Extract of cascara, 10 grains (0.6 Gm.), is given on admission, followed by 1 ounce (30 Gm.) of magnesium sulfate by mouth two hours later.

5. Magnesium sulfate, 1 ounce, is given every morning for three days, unless there have been more than four bowel movements the previous day.

6. Alkalis in the form of imperial drink (*potus imperialis*, British Pharmaceutical Codex) are given three times daily.

7. Spinal fluid drainage is done as soon after admission as possible and may be repeated as often as is indicated.

8. Fifty cc. of 50 per cent dextrose is given intravenously from two to four times a day.

9. Ten cc. of 50 per cent magnesium sulfate is given intramuscularly one to two times a day for two days.

10. Caffeine with sodium benzoate,  $7\frac{1}{2}$  grains (0.5 Gm.) is given hypodermically every four hours for six doses. If indicated, this procedure may be repeated.

11. The patient is digitalized in from thirty-six to forty-eight hours and is then placed on a maintenance dose.

12. Paraldehyde (100 per cent), 3 or 4 drachms (from 11 to 15 cc.), is given from one to three times a day for sedation. Intravenous sodium amytal may be used, though we would hesitate to recommend that more than from 10 to 15 grains (0.6 to 1 Gm.) be given to any one patient. Hydrotherapy is indicated wherever possible.

13. A high caloric soft or liquid diet, supplemented by vitamin containing substances—especially of the B group—is ordered. If the patient has difficulty in retaining nourishment, gastric lavage with a sodium bicarbonate solution should be done.

14. Fluids are given according to the patient's desires. The factor of the patient's comfort should be the determining one in governing the amount of fluids given.

15. Should the patient be asleep, he is not awakened for any reason, medicinal or otherwise.

We consider that the delirium tremens patient has recovered sufficiently to be discharged from the hospital when his delirium has ceased, his tremor is absent or markedly diminished, his apprehensiveness has disappeared, his appetite is definitely improving, his general physical condition is such as to permit him to be ambulatory and—most significant of all the prognostically favorable signs—he is able to obtain a good night's sleep without or with a minimum of sedative aid. With these criteria for discharge, and with the regimen that we have described, the average duration of our patients' stay in the hospital has been 4.8 days.

This method of treating delirium tremens has been considered worthy of description because of the reduction in the mortality and in the duration of the disease that it has brought about in our wards at the Cincinnati General Hospital. There are a number of items in this treatment—some of them based on an etiologic approach, others symptomatic in their efficacy. We realize that in private practice it is not always a simple matter to hospitalize patients and that it is frequently impossible to obtain the patient's cooperation in a regimen as intensive as the one we have proposed. Nevertheless, we present it as the most effective treatment for delirium tremens that we have been able to find. In cases in which the entire regimen cannot be utilized, it should be approximated as closely as possible.

Concerning those cases which might be classified as impending delirium tremens, it is probable that one might compromise and use only parts of the treatment with a measure of safety. It has been our habit, however, to treat these individuals precisely as though they were active cases, and it is our belief that by so doing we have aborted a large number of attacks, some of which might have had unfavorable outcomes had we temporized.

5. Blotner, Harry: *Effect of Alcohol on Digestion by Gastric Juice, Trypsin and Pancreatin*, J. A. M. A. 106: 1970 (June 6) 1936.

single doses of from 800 to 1,100 roentgens and total doses of from 10,000 to 12,000 roentgens. He emphasizes, however, that the aforementioned doses cannot be applied schematically in all cases but must be varied according to the localization of the nevus, the ray sensitivity of the skin (estimated on the basis of the intensity of the reaction), the size of the nevus, the age of the patient and the depth or superficiality of the nevus. After discussing and illustrating the adjustments in technic and dosage that may become necessary, he cites the results obtained at his clinic. He concludes that, if properly applied, the borderline rays are at present the best therapeutic method for naevus flammeus.

**Roentgen Rays and Cholesterol Content of Blood.**—Schumacher and Rusch made tests on the blood and serum of forty women, twenty-five of whom had carcinoma or sarcoma and fifteen of whom were definitely free from carcinoma. These tests did not corroborate the results of Levy-Dorn and Burgheim. The authors failed to detect fluctuations in the cholesterol content of the blood after roentgen irradiation. Moreover, they found no connection between cholesterol content and roentgen intoxication and no difference in the behavior of the blood of patients with or without cancer.

Pathogenic Significance of Types of Pneumococci. H. Grossmann.—p. 38.

\*Diphasic Nature of Typhoid Bacilli. F. Kauffmann.—p. 103.

**Nephelometric Determination of Watering of Milk.**—Kyriazidis shows that the fat content of milk is the essential factor in its turbidity. The various protein substances (casein, lactoglobulin and lactalbumin) are a much weaker turbidity factor and are subject to only minor changes. It has been proved that the fat content makes up about three fourths of the turbidity and the other substances only about one fourth. Because of this predominance of the influence of fat, the reduced permeability of a watered milk does not exceed that of a milk with a reduced fat content. However, if the fat is eliminated, the turbidity of the defatted milk is influenced by watering to a much greater extent. For this reason the author tested the constancy of the nephelometric values of defatted milk and determined its modification by watering. He fills a centrifuge tube of 30 cc. capacity to four fifths of its volume. Then this tube is closed with a rubber stopper, through which two hollow needles pass, one reaching approximately the lower third of the tube and the other slightly below the fat layer that is formed by centrifugation. Centrifugation is continued for fifteen minutes at 3,000 revolutions per minute. After this, from 4 to 5 cc. of milk is slowly withdrawn through the longer needle. The defatted milk thus obtained is diluted at 15 C. in a ratio of 1:10. Then it is placed into a glass cuvette (1:5:5) and its permeability is determined by means of Moll's extinc-tiometer. The amount of water is determined with the aid of a curve. Finally the detected quantity of water is calculated for one liter. In this calculation the quantity of fat must of course be taken into account. The author stresses that this method of nephelometric control of the watering of milk is superior to the chemical methods that are usually employed. It is not only simple and quick but also more exact than the chemical methods.

**Diphasic Nature of Typhoid Bacilli.**—Kauffmann directs attention to the fact that the serologic Salmonella types, in consideration of their flagellata antigen (H-antigen) have been divided into two groups: (1) the monophasic types, that is, the types that are present in only one phase, and (2) the diphasic types, which occur in two phases and represent two different serologic manifestations of one and the same type. The typhoid bacilli have heretofore been regarded as monophasic, because only one phase with a single H-antigen could be demonstrated. The paratyphoid B bacilli, however, proved diphasic. Since Japanese investigators had observed a change in phases

in typhoid bacilli, the author made additional studies. He found that there is a second phase of typhoid bacilli, which is characterized by a specific flagellata antigen. This new flagellata antigen could be demonstrated only in typhoid bacilli and not in other Salmonella types. The author emphasizes that he uses the term phase only for two different serologic manifestations of the flagellata antigens, whereas he applies to the different serologic manifestations of the body antigens the term forms.

### Wiener klinische Wochenschrift, Vienna

49: 1481-1512 (Dec. 4) 1936

\*Treatment of Hematemesis and Melena with Unrestricted Diet. E. Meulengracht.—p. 1481.

Calculus Formation in Spleen After Malaria as Cause of Disorder. R. Meyer.—p. 1496.

**Treatment of Hematemesis and Melena with Diet.**—Meulengracht says that five years ago he decided to change the customary treatment of bleeding gastric ulcers from a greatly restricted to a practically unrestricted diet. The reasons which induced him to change the former treatment were that patients died of exhaustion after hemorrhages in spite of perhaps as the result of scrupulous dieting, that occasionally patients with protracted hemorrhage stopped bleeding when they were given food, and that ambulatory patients with severe melena frequently recovered without changing their diet. Moreover, it seemed to him inadvisable to let a patient starve at a time when, as the result of the shock of hemorrhage, the intake of fluids, salts, vitamins and sufficient calories seemed especially necessary. The diet recommended by the author is a so-called full purée diet. The patients are given five meals a day and are permitted to eat as much as they want. Foods are selected that will not cause irritation and are readily digestible. The noon meal includes a variety of dishes; namely, soups, meats, vegetables and fruits. The other meals consist of bread and butter, gruels, milk and so on. Milk is given also between the meals. The daily number of calories averages about 2,300. Three times daily the patients are given a teaspoonful of a mixture of 15 Gm. of sodium bicarbonate, 15 Gm. of magnesium subcarbonate and 2 Gm. of extract of hyoscyamus; a tablet of iron lactate is also given three times each day. With this method of treatment the author had only three fatalities in 273 cases of massive hemorrhages from gastric ulcers or erosions. In comparison with other statistics, which report a mortality of from 7 to 10 per cent, the mortality rate of his material is unusually low. After discussing the advantages of his treatment and the blood regeneration, he points out that, if with his method of treatment the mortality of bleeding gastric ulcers can be reduced to about 1 per cent, a surgical intervention will hardly be necessary during the hemorrhagic stage. To be sure, an operation for the gastric ulcer may become necessary at a later date.

**Acute Appendicitis Past Middle Age.**—According to Bondarenko, 2,888 cases of acute appendicitis were admitted to the third surgical clinic of the Second Leningrad Medical Institute between 1919 and 1934. Of the patients 410, or 14.2 per cent, were past 40 years of age. An analysis of the incidence and of the clinical course of this group shows that acute appendicitis is almost as frequent in this age as in the younger

## THE COMPREHENSIVE MANAGEMENT OF DELIRIUM TREMENS

INCLUDING A TREATMENT UTILIZED IN THREE  
HUNDRED CONSECUTIVE CASES

PHILIP PIKER, M.D.

Alfred M. Stern Assistant Professor in Psychiatry, University of  
Cincinnati College of Medicine  
AND

JESS V. COHN, M.D.

HOLLYWOOD, FLA.

The fact that delirium tremens may result fatally is frequently overlooked by the practicing physician. In a survey of the available literature as far back as 1910, one finds that the statistics concerned with delirium tremens show a considerable mortality, the peak being reached in one reputable clinic which reported 37 per cent.<sup>1</sup> Recently the death rate has diminished considerably, undoubtedly because of more intelligent treatment of these cases, so that the mean mortality in the past ten years has been approximately 10 to 12 per cent. It is because rational management of this disease apparently has produced favorable results generally and in the hope of stimulating an effort to bring about a further reduction in the death rate that this report is being made.

Because of the traditional negligence with which medical statistics are usually compiled, it is not possible to evaluate accurately a comparison between the results reported by other clinicians and those accomplished by us in the psychiatric division of the Cincinnati General Hospital during the past two and a half years. Nevertheless, that our cases offered no better prognosis on admission than did those concerning which reports have been made from other clinics is suggested by the probability of a nutritional caliber which is lower in patients admitted to the Cincinnati General Hospital than in the general population, the probability of a greater incidence of other coincidental pathologic processes in our patients, and the fact that (because of the crowded conditions at the hospital) only those individuals are admitted by the receiving physicians who are definitely too ill to be cared for elsewhere. With these factors in mind, we feel that our crude death rate of 5.3 per cent is significant and that our method of accomplishing this reduction merits consideration by those physicians who are called on to manage patients with delirium tremens.

This report has to do with 300 consecutive cases that were admitted to the Cincinnati General Hospital from Jan. 1, 1933, to July 1, 1935. The cases included

in this series were limited to those concerning which there was no question as to diagnosis. Cases presenting impending delirium tremens were excluded, though they received the same treatment as did the active cases. The presence of a complicating disorder—pneumonia, fracture, gastric hemorrhage and the like—was not considered a significant factor in the selection of patients, so that the sole prerequisite to inclusion in this series was the definite diagnosis of active delirium tremens, regardless of what other pathologic process might be coexistent.

The treatment that we employ involves no principle or medication that is essentially an innovation. We have culled over the therapeutic suggestions that have been made by various physicians<sup>2</sup> and have attempted to organize therefrom a regimen which would include the more rational and effective measures of each. Our choice of procedures has been limited, of course, by the circumstances under which we find ourselves at the Cincinnati General Hospital. We realize that our management of these cases could be improved in a

fects but whose bladder is infected with an alkali-producing organism. Another source of error in using the bladder urine  $p_H$  as an indication of the renal acidity is in a situation in which one kidney has diminished function, obstruction or infection. Here the bladder urine  $p_H$  represents the average of the urine of the two sides, one of which may be normal and giving a low  $p_H$  while the diseased stone-bearing kidney may yield a urine with a higher  $p_H$ . That this is true was proved by actual simultaneous measurement of the  $p_H$  of the urine from the renal pelvis by the electrical method. In some instances there was a difference between the normal and the diseased sides measuring up to 0.6  $p_H$  unit. It is obvious that, when a stone-bearing kidney has a markedly diminished function or a severe infection with alkali-producing, urea-splitting organisms, little relief can be expected from this type of therapy unless one can actually demonstrate a sufficiently low  $p_H$  in the pelvic urine.<sup>8</sup> This deduction assumes the premise that the reported good results are dependent on the production and maintenance of a low  $p_H$ .

**Renal Function.**—In order for a kidney to excrete a urine with a  $p_H$  which markedly deviates from the normal range (infection excluded), that kidney must have the ability to excrete and concentrate acid or alkaline ions in sufficient quantity. If the kidney function is too impaired to do this, the urinary  $p_H$  will tend to approach that of blood and there will result a piling up of the excess acid or alkali in the blood stream with a resultant acidosis or alkalosis. This has been clinically demonstrated by one of us<sup>9</sup> in discussing acidifying salt therapy.

A satisfactory acid  $p_H$  level was obtained usually only in those cases in which the kidney function was shown to be adequate by specific gravity tests indicating sufficient concentrating ability. However, there was an occasional patient who exhibited a low  $p_H$  in the presence of a low specific gravity. Theoretically and practically the buffering reaction of such a urine is so poor that the total amount of acid is indeed very small. Such a dilute urine with low  $p_H$  but with a poor buffering power cannot be expected to exert a strong solvent action.

It is evident that the use of the type of therapy under discussion is distinctly limited to those patients whose stone-bearing kidney can maintain adequate function and can concentrate a sufficiently acid urine. As previously noted, kidneys infected with certain *Staphylococcus albus* or *B. proteus* organisms will also fail to have a sufficiently acid urine.

#### SUMMARY OF RESULTS

Twenty-seven patients were on the diet for from six to sixteen months, an average duration of eleven months. Twenty of these maintained a mean bladder

8. For example, E. G., a woman, aged 46 (case 11) Dec. 28, 1934, had an  $p_H$  of 5.2 for a calculi of calcium carbonate and an  $p_H$  of 5.4 for the right kidney, which kidney was a 25 cc. infected hydronephrosis. Control showed two fragments in the kidney. The patient was placed on the diet April 2, 1935. May 5, roentgenograms showed an oval concretion 1.5 by 1 cm. in the right kidney.

Cystoscopy: Bladder  $p_H$  —5.18

Specimens	Right	Left
1. $p_H$	5.44	5.13
2. $p_H$	5.49	5.06
3. Culture	<i>B. Proteus</i>	Negative
4. Microscopic study	Many bacteria	Negative
	Triple phosphate crystals	
	0.5%	0.5%
5. Urea		

It will be noted that, if judged by the bladder urine, the  $p_H$  is sufficiently low. Actually the right kidney urine  $p_H$  is above the optimum level for satisfactory results.

9. Oppenheimer, G. D.: Dangers of Acidifying Salt Therapy in Urologic Cases, *J. Urol.* 33: 22-27 (Jan.) 1935.

$p_H$  of 5.2 or under. In none was a complete or partial solution (disappearance) of the urinary calculus noted on the frequently controlled x-ray films. Five patients showed an increase in size of their renal calculi and in one patient a new stone formed while on the regimen.

In our hands, the high vitamin acid ash diet has not caused a disappearance or reduction in the size of renal calculi of the alkaline earth type.

#### URINARY EXCRETION OF GONADOTROPIC HORMONE IN CRYPTORCHIDISM

JULIUS H. HESS, M.D.  
RALPH H. KUNSTADTER, M.D.  
AND  
WILLIAM SAPHIR, M.D.  
CHICAGO.

Numerous investigators<sup>1</sup> recently have reported favorable results in the treatment of undescended testes with gonadotropic substance. There has arisen a good deal of justifiable skepticism, however, as regards the value of this form of treatment in unselected cases. Where there is a mechanical factor preventing the normal descent of the testes the administration of gonadotropic substance cannot be expected to bring them down.

Engle<sup>2</sup> has brought forward evidence as to the hormonal nature of the factors controlling the natal descent of the testes in the human being. That the gonads in turn influence the functional activity of the hypophysis has been shown by Nelson.<sup>3</sup> This worker has reported that, as the testes of rats which are rendered cryptorchid undergo retrogressive changes, the hypophysis in these animals exhibits changes similar to those found after castration. The injection of gonadotropic factor from pregnancy urine (antuitrin-S) into these animals results in the stimulation and restoration of the seminal vesicles and prostates, while the hypophysis shows a disappearance of the castration cells. There is no change in the epithelium of the seminiferous tubules but there is a marked stimulation of the interstitial tissue of the testes. The treatment of a series of castrate rats with gonadotropic factor extracted from pregnancy urine resulted in no change in the hypophysis and sex accessories. Nelson believes that the testes play an intermediary rôle in the influence exerted on the pituitary and sex accessories. This may be exerted by the secretion of the testis hormone or by estrogen, either secreted directly by the testis or converted from the testis hormone.

It is apparent that cryptorchidism of endocrine origin, whether it stands in a causal or a secondary relationship to pituitary dysfunction, should be accompanied by evidence of such dysfunction. It is generally agreed that

From the Department of Metabolism and Endocrinology of the Nelson Morris Institute and the Pediatric Endocrine Clinic of the Michael Reese Hospital.

The authors are indebted to Dr. Samuel Soskin for his helpful suggestions and to Miss Rita Neilson, R.N., for her cooperation and aid in the management of clinic patients.

nary doses have seemed to have practically no sedative value, and we have hesitated to give representatives of this group in repeated large doses because of the depressing effect on the circulation.

When all our routine measures have failed to secure rest in a patient, we have occasionally administered one dose of sodium amytal intravenously, to the extent of from 10 to 15 grains (0.6 to 0.9 Gm.), with fairly good results. Because our use of this drug is limited by the small supply available at the hospital, we have employed it only as a last resort. Using it thus in those cases which were most refractive to ordinary sedative measures does not justify a comparative evaluation as to its efficiency. It is quite possible that, were one dose of sodium amytal given as a routine and early, it might induce therapeutic sleep considerably sooner than do the usual sedatives.

Another procedure that has a certain amount of indirect sedative effect is spinal fluid drainage. Lumbar punctures are done as a routine in our cases at the beginning of their stays in the hospital. When a delirium tremens patient shows no sign of improvement within forty-eight hours after treatment is instituted, a second lumbar puncture with drainage of the spinal fluid will not infrequently diminish his restlessness sufficiently to permit him to sleep. In the same category—namely, of procedures tending to promote rest by reducing intracranial pressure—are the administration of intravenous dextrose, intramuscular and oral magnesium sulfate, and hypodermic caffeine.

It has been our custom to be quite cautious in the selection of sedative medication. We are aware that bromides, chloral, tribrom-ethanol and other compounds have been warmly recommended and are indeed in more or less common usage by physicians who report good results. Our policy, however, has been to avoid so far as is reasonable the possibility of adding insult to already injured tissues. So we abstain from chloral because of the likelihood of an already intoxicated heart; from tribrom-ethanol because of the comparatively great incidence of liver disease in chronic alcoholic patients; from bromides because the large doses necessary to be effective occasionally may produce intoxications in their own right; and so on. It may be that we are unduly careful; but, on the other hand, it is possible that our elimination of most of the commonly used sedatives has had something to do with the lowering of our death rate.

At this point we would stress the contraindication to morphine that exists in the management of these cases. It has been definitely established<sup>3</sup> that morphine increases intracranial pressure. A case in point is included in this series. The patient was admitted to the medical service suffering from profuse gastric hemorrhage, probably ulcerous etiologically. He was given morphine, quite properly, every four hours for twelve doses, after which he developed delirium tremens and was transferred to the psychiatric service. On lumbar puncture 150 cc. of spinal fluid under exceedingly great pressure was obtained; the intern withdrew the needle not because of a diminution in the flow but because he was, as he said, "afraid to remove more fluid." The next day 65 cc. was obtained, and on the third day 75 cc. The probability of a causal relationship between the morphine this patient had received and the amount of spinal fluid obtained from him—the largest amount

we have been able to remove from any alcoholic patient admitted to our wards—is to be considered quite pertinent.<sup>4</sup> That morphine increases the chances of death in a case of delirium tremens is not to be doubted. In the psychiatric service of the Cincinnati General Hospital the cardinal sin that can be committed by an intern is the ordering of morphine for a patient with delirium tremens.

There is one other procedure calculated to promote rest which is to be highly recommended in cases of this type, though we have been unable to include it in our regimen because of lack of facilities and a paucity of personnel. We refer to the use of hydrotherapy, which has been reported quite helpful and which offers a method of sedation which adds not at all to the patient's toxicity.

Also worthy of mention at this point is the contraindication to mechanical restraint, except as it may be necessary as part of a hydrotherapeutic maneuver. A sufficiently numerous staff of nurses and orderlies, together with the use of hydrotherapy, would practically eliminate the need for shackles, restraining jackets and the like. In our wards, because of our limited facilities, it is almost a routine to shackle patients with delirium tremens. With us it is the lesser of two evils. We feel that, could we make this unnecessary, we would remove what is definitely a physical and emotional irritant, and consequently increase the patient's chances for recovery and shorten his stay in the hospital.

#### PROMOTION OF ELIMINATION

We need not dwell long on the obvious importance of elimination. To rid the bowel of any accumulated sources of toxicity and for general purgative measures, a single dose of cascara followed by daily doses of magnesium sulfate is recommended. In addition, it is necessary to maintain an active kidney function in order to eliminate as rapidly as possible the accumulating products of a disordered metabolism. Here the caffeine, the intravenous dextrose and in some measure the digitalis provide the necessary diuretic stimuli.

#### DECREASE OF INTRACRANIAL EDEMA AND PRESSURE

That there is an irritation and edema of the brain and meninges and an increase in intracranial pressure in delirium tremens has been demonstrated clinically and in the autopsy room sufficiently often to need no further discussion at this time. It is exceedingly important that we combat these pathologic conditions as intensively as possible, first because of their existence *per se* and secondly because sedatives are much more likely to be effective when the brain is less toxic and irritable. The most simple direct method of decreasing intracranial pressure is by spinal fluid drainage. We recommend that this be done as soon as possible and that the fluid be allowed to escape slowly until the drops are quite far apart. Although the edema of the brain is not always reflected by an increase in spinal fluid pressure in delirium tremens, we feel that the drainage of as much fluid as is readily removable, whether 5 or 50 cc., is likely to be of some aid. Concerning the factor of safety in the complete reduction of pressure by the removal of as much fluid as possible, we can report that in the approximately 1,500 cases of acute alcoholism and delirium tremens that we have

3. Kennedy, Foster, and Wortis, S. B.: *Modern Treatment of Increased Intracranial Pressure*, J. A. M. A. 96:1284 (April 18) 1931.

4. Nuzum, Frank, and LeCount, E. R.: *The Ability of Brain Tissue to Take Up Water in Delirium Tremens and Other Conditions*, J. A. M. A. 67:1822 (Dec. 16) 1916.

bilateral undescended testes or of at least one functionally active testis.

On the basis of this, the five bilateral cases showing an increased excretion of gonadotropic hormone may be regarded as cases in which the gonadal mechanism has failed to function but in which the pituitary is still active. The administration of anterior pituitary-like substance in these cases resulted in a descent of the testes and the development of other signs of gonadal stimulation. Following the establishment of gonadal function, the excretion of gonadotropic hormone returned to the level below which it could not be demonstrated by the Zondek precipitation method.

The eight cases, three unilateral and five bilateral, in which gonadotropic hormone was not excreted before treatment are of particular interest. The presence of a normal testis in the three unilateral cases must be interpreted as indicating the presence of a normally functioning pituitary and also explains the absence of the gonadotropic hormone in the urine.

The failure of two of the three unilateral cases to respond to treatment is attributed to the presence of a mechanical obstruction.<sup>9</sup> In the other unilateral case the administration of the anterior pituitary-like factor was followed by descent of the testis into the scrotum. Unquestionably there was no mechanical obstruction and the success of therapy might be explained by the stimulation of an underdeveloped testis. Three patients with bilateral cryptorchidism who showed no clinical evidence of pituitary dysfunction and who did not excrete gonadotropic hormone in the urine responded rapidly to treatment (cases 7, 8, 9). The testes descended well into the scrotum in six, four and four weeks, respectively. In these cases there was no mechanical obstruction and evidently the undescended testes were sufficiently developed to utilize the pituitary gonadotropic hormone from the blood, with stimulation and descent following therapy.

The absence of the gonadotropic hormone in two of the five bilateral cryptorchids may be interpreted as indicating a primary pituitary dysfunction, as both cases (5 and 10) showed clinical evidence of infantilism. In these cases the administration of the anterior pituitary-like factor failed to bring the testes down.

#### SUMMARY AND CONCLUSIONS

The determination of the gonadotropic hormone in the urine of thirteen boys with cryptorchidism revealed the presence of significant amounts of the hormone in the urine of five of these boys. These results are consistent with the belief that the latter cases resulted from a failure of the gonadal mechanism, the pituitary gland being functionally active. These cases responded to treatment with the use of the anterior pituitary-like factor by descent of the testes and disappearance of the hormone from the urine.

Three cases of unilateral cryptorchidism in which the descended testis was apparently normal did not show any increased excretion of gonadotropic hormone prior to treatment and only one of these three (case 2) responded to treatment by descent of the other testis.

Two of the five cases of bilateral cryptorchidism which showed no gonadotropic hormone before treatment and which did not respond to treatment with

anterior pituitary-like substance were interpreted as cases of primary pituitary dysfunction, as both cases (5 and 10) showed clinical evidence of infantilism. The other three cases with no clinical evidence of pituitary dysfunction that responded to treatment must be explained on the basis of functionally active undescended testes.

If the results of our small series of cases are borne out by future observations, they indicate a possible sphere of usefulness for the determination of the urinary gonadotropic hormone in the prognosis of cryptorchids under treatment.

In view of these observations we believe that in many instances the determination of the gonadotropic hormone in the urine is a valuable procedure in determining both the type of treatment and the prognosis. The presence of the hormone in the urine justifies medical treatment and offers a good prognosis in the absence of mechanical obstruction. The absence of the hormone in the urine of bilateral cryptorchids may be due to: 1. Functionally active testes, although abnormally placed; they offer a good prognosis following endocrinotherapy in the absence of mechanical obstruction. 2. Primary pituitary dysfunction, in which case functional results will be questionable. Absence of the hormone in the urine of unilateral cryptorchids indicates adequate gonadal function in at least one testis. Organotherapy should be tried in both 1 and 2; in the event of failure, surgery is indicated.

## INCREASE IN HEIGHT AND WEIGHT AND DECREASE IN AGE OF COLLEGE FRESHMEN

OVER A PERIOD OF TWENTY YEARS

LAURENCE B. CHENOWETH, M.D.  
CINCINNATI

Sufficient material is not available on which to base an accurate opinion of the stature and weight of ancient and medieval men. It is said that the height required for a recruit for the ancient Roman cavalry and for the first cohorts was 5 feet 10 inches,<sup>1</sup> Roman measure.<sup>2</sup> Men of smaller stature were accepted for other less important cohorts.<sup>3</sup> From a study of about 300 thigh bones Parsons<sup>4</sup> estimated that the midland English male of the thirteenth to the fifteenth centuries averaged 65.75 inches (167 cm.) and the female 63 inches (160 cm.) in height.

In 1921 Clelia Mosher noted that the height of Stanford University women students had increased 1 inch (2.5 cm.) in thirty years.<sup>5</sup> In 1926 Czechoslovakian children were found to be one year advanced in size over what they were thirty years before.<sup>6</sup> In 1927 Gray found American boys of American born parents to be more than 2 inches taller than the same

9. Since this paper went to press, the two boys with unilateral cryptorchidism (cases 12 and 13) were operated on and the testes in each instance were found to be embedded by thick adhesions below the internal ring. The testes were atrophic but were successfully placed into the scrotum. Anterior pituitary-like substance was administered to each boy one month after operation, followed by an increase in the size of the testes.

Let us reemphasize the fact that there is a considerable mortality associated with delirium tremens and that there is a considerable danger attached to the negligent management of such cases.

## SUMMARY

Three hundred consecutive cases were treated by a comprehensive method of therapy for delirium tremens in the psychiatric division of the Cincinnati General Hospital with a resultant crude mortality of 5.3 per cent and an average stay in the hospital of 4.8 days.

ATTEMPTED SOLUTION OF RENAL  
CALCULI BY DIETETIC  
MEASURES

GORDON D. OPPENHEIMER, M.D.  
AND  
HERBERT POLLACK, M.D.  
NEW YORK

Higgins<sup>1</sup> has reported the successful solution of renal calculi in human beings. The method employed was the administration of an acid ash diet supplemented by vitamins A, B, D, G and E from several sources. This work was based on the earlier reports of many investigators<sup>2</sup> and also on his own animal experimentation.<sup>3</sup>

The preliminary reports published by Higgins were so promising and of such clinical importance that a parallel series of patients was treated by the method he outlined. The medical aspects as well as the diet supervision and the urinary  $p_H$  measurements were controlled in the nutrition clinic of the dispensary. A representative of the surgical service cooperated, selected the cases and performed the necessary genito-urinary procedures.

The diet as employed in this work differed somewhat in detail but not in principle from that used by Higgins. This was necessitated by the fact that the majority of the patients were financially unable to buy the more expensive foods. The simplification to be described later was therefore needed. The following is a standard regimen as outlined to the patient: A diet outline reproduced here (table 1) was given to each patient. This called for the ingestion of three regular meals daily. Each patient was instructed individually in the manner of preparation of the food and the limitations as to variation from the fixed diet. The diets were prescribed salt free whenever possible. In the case of the "kosher" Hebrew patients with whom the salting of the meat is a ritual, an effort was made to have the meat thoroughly washed in running water after its

preparation. The total fluid intake was restricted to 1,800 cc. daily in order to prevent excessive dilution of the excreted urinary acids. The patients visited the clinic every week for the first few months and bimonthly thereafter. The  $p_H$  and specific gravity determinations were made at each visit if possible.

When the  $p_H$  of the urine could not be brought down to the desired level by this diet alone, ammonium chloride up to 6 Gm. daily was given in divided doses. However, it should be pointed out that only in occasional cases did the ammonium chloride succeed in changing the urinary  $p_H$  when the diet failed to do it alone. It must be mentioned at this point that the use of the acid sodium phosphate as an acidifying drug was considered bad practice in patients with grossly infected urine. This salt increases the phosphate concentration of the urine. In the presence of an alkaline urine it is easily seen that the formation of phosphatic incrustations and depositions may be facilitated by an increased phosphate concentration. Ammonium chloride is to be preferred in these cases. Most alkaline stones contain phosphates. It is poor chemical practice to attempt to dissolve a salt by the same acid radical from which it was formed. A further consideration is that calcium phosphate is insoluble whereas calcium chloride is quite soluble.

As will be noted, the diet is poor in vitamins. The vitamin supplement was supplied to the patients gratuitously at their dispensary visits through the courtesy of Mead Johnson & Co. Vitamins A, B, D, G and E were used in the form of halibut liver oil 30 drops daily for the first month and 10 drops daily thereafter, wheat germ embryo one-half ounce (14 cc.) daily, and brewers' yeast tablets 36 grains (2.3 Gm.) daily in divided doses.

TABLE 1.—Diet Outline

Use no more than 1 pint of milk a day.		
Breakfast:		
4 tablespoonfuls of cooked cereal with milk and sugar		
2 eggs		
2 slices of bread and butter (2 teaspoons)		
Lunch:		
$\frac{1}{4}$ pound of meat or fish		
$1\frac{1}{2}$ cups of macaroni, spaghetti or noodles		
Rice pudding, custard, bread pudding, cornstarch pudding or french toast		
2 slices of bread and butter		
Supper:		
$\frac{1}{4}$ pound of meat or fish		
$1\frac{1}{2}$ cupfuls of macaroni, spaghetti or noodles		
$\frac{1}{2}$ cupful of vegetables (from list)		
1 portion of plain cake		
2 slices of bread and butter		
Bedtime:		
4 tablespoonfuls of cooked cereal with milk and sugar		
Use no salt		
Eat only the following foods:		
Cornmeal	Sweet butter	Corn, fresh
Oatmeal	Beef	Turnips
Rice	Beef liver	Squash
Whole wheat bread	Lamb	Onions
Macaroni	Veal	Tea
Spaghetti	Halibut	Coffee
Noodles	Codfish	Sugar
Eggs	Mackerel	

Fifty-two patients have been treated since the diet was first used in this clinic sixteen months ago. Twenty-seven of these patients have been on the regimen for from six to sixteen months in an attempt to cause solution of their renal calculi. These calculi were all radiopaque. In thirteen cases (table 2) the probable chemical composition was indicated by analyses of stones, either removed at a previous operation or

At the time of physical examination the age is recorded in years and months, the height in tenths of an inch and the weight to the nearest pound. All students, men and women, are measured in their bare feet. The men are entirely stripped when weighed, and the women are weighed in a light cotton flannel examining gown. This gown is the same size and weight today as it was twenty years ago. Examinations were performed between 9 a. m. and 5 p. m. Freshmen students were examined each year between July 1 and November 1; the great majority of them were examined in the month of October.

The accompanying table is a summary of the average heights, weights and ages of entering freshmen students from October 1916 to June 1936. The total number of individual students measured was 13,092, of whom 8,968 were boys and 4,124 were girls. By a study of this table one notices a significant trend in stature and weight, which is graphically illustrated in charts 1 and 2.

By consulting chart 1, a gradual increase in height is to be noted. Men freshmen entering in 1935 were 1.78 inches (4.45 cm.) taller than those entering in 1916, and women freshmen in 1935 were 0.79 inch (2 cm.) taller, on an average, than those admitted in 1916. The tallest girls were found in the freshman class of 1933-1934.

A similar increase was noted for weight. Chart 2 represents the average weight of freshmen for each academic year. The curves show that there has been a gradual increase in weight in all students but that the increase has been greater for men than for women. The heaviest boys and girls were admitted in the academic year 1933-1934.

In order to evaluate properly the significance of the changes in height and weight it was necessary to plot

*Average Height, Weight and Age of Freshmen at the University of Cincinnati*

Academic Year Examined	Men				Women			
	Number Measured	Age, Years	Height, Inches	Weight, Pounds	Number Measured	Age, Years	Height, Inches	Weight, Pounds
1916-1917	150	19.45	67.45	132.05	153	18.87	62.93	119.00

1933-1934	231	18.99	69.14	149.07	310	18.65	64.21	122.56
1934-1935	390	18.77	69.14	143.41	353	18.44	63.73	121.89
1935-1936	456	18.83	69.23	141.79	331	18.60	63.72	120.68

the average age for each year. The age is recorded in years and months on the examination form, but in making the averages age was considered at the nearest birthday.

By consulting chart 3, one notes that the general tendency of the curves is downward, especially in the case of the men. At the present time, men freshmen are slightly older than women freshmen. However, the men have shown a greater decrease in age on

admission than the women have. The academic year 1918-1919 was the only one in which the boys in college were younger than the girls, and it will be remembered that boys 18 years of age and older were being drafted for the army at that time.

#### SUMMARY AND CONCLUSIONS

1. The height, weight and age of 8,964 young men and 4,124 young women entering the University of Cincinnati from 1916 to 1935 were averaged each year.

Chart 3.—The age of freshmen at the University of Cincinnati at the time of their examinations, arranged by academic years from 1916 to 1936. The curve has been smoothed to show the general trend. Averages have been plotted with the same symbols as in chart 1.

2. The results showed that freshmen are admitted at a younger age now than they were twenty years ago.

3. Freshmen are taller and heavier today than they were twenty years ago, in spite of their younger age.

4. Judging from evidence from the past, mankind in civilized countries is steadily growing taller.

5. There is no definite answer to the question of what causes this to be true, but the probable causes of the increase in stature and weight of young people are better nutrition in infancy and childhood, less communicable disease, higher standards of living, and a higher degree of health intelligence among people in general. Undoubtedly those who have contributed most to this state of affairs have been physicians (especially pediatricians), nutritionists, public health workers and educators.

6. Studies in the end product of the public schools (college freshmen) seem to indicate that a definite racial betterment is taking place in the United States and that the improvement is only partially influenced by social and economic position.

**Silicosis and Tuberculosis.**—It is remarkable that a simple inorganic compound such as dioxide of silicon ( $\text{SiO}_2$ ) can set in motion a complicated series of cellular reactions comparable to those produced by a living organism made up of proteins, carbohydrates and lipoids. Each one of these components is customarily assigned a special rôle in the production of the tissue reaction to the tubercle bacillus. The proteins are known to stimulate exudation from the blood vessels; the lipoids, proliferation of fixed tissue elements; and the carbohydrates determine humoral changes. Furthermore, these major elements have been split into a number of chemical fractions which on injection into animals have produced either exudative or proliferative tissue responses. The validity of these observations has not been questioned, but it is at least debatable whether or not the tubercle bacillus excites a given cellular reaction because of the presence of some fatty acid that can be extracted from it by chemical manipulation.—Gardner, L. U.: The Similarity of the Lesions Produced by Silica and by the Tubercle Bacillus, *Am. J. Path.* 13:13 (Jan.) 1937.

passed spontaneously. They varied in number and size from small single stones to multiple or large dendritic stones. A number of cases are under treatment to prevent recurrence of stone formation following operation, but these cases have not been included in the series.

Patients were discharged from the regimen for lack of cooperation, because of poor concentrating ability of the kidneys, or because of evidence of renal impairment, i. e., azotemia. In two patients, uremia with acidosis seemed to be precipitated by the acidifying regimen. Both of these patients died within six weeks in uremia, necropsy showing bilateral calculous pyonephrosis. Patients also were discharged in whom the diet or medication was not tolerated by the gastrointestinal tract or in whom pathologic changes in this tract contraindicated the treatment.

The clinical course of twenty-seven patients who adhered to the regimen for from six to sixteen months is given in table 2. The average duration of the therapy for this group was eleven months. All the patients either maintained their normal weight or gained in weight. As will be noted from the table, these patients did not show evidence of hyperparathyroidism as indicated by the calcium, phosphorus and calcium ion concentrations in the blood.<sup>4</sup> The blood studies on patient E. R. (case 17, table 2) indicate calcium values at the upper limit of normal. To rule out hyperparathyroidism, twenty-four hour urinary calcium excretions were determined. On an intake of 110 mg. of calcium daily the patient excreted 130 mg., which is well within normal limits.

#### THEORETICAL PRINCIPLES

A discussion of the theoretical principles involved in the use of the regimen may be in order.

1. *Use of Vitamin A in the Solution of Calculi.*—The etiologic factors in the formation of urinary calculi are not all known. However, as previously stated, the experimental work, particularly in rats, has shown that a vitamin A deficiency in the diet may play an important rôle. This phase has recently been comprehensively reviewed by the Council on Pharmacy and Chemistry.<sup>5</sup> In brief, urinary calculi are apparently formed in rats on the basis of epithelial changes of the lining surface of the calices, pelves and bladder, mainly a hyperkeratosis. Exfoliated keratinized epithelial masses are supposed to act as a nucleus for crystalline deposits in an alkaline urine. The latter is a concomitant finding with vitamin deprivation, particularly vitamin A. Fujimaki,<sup>2</sup> Saiki<sup>6</sup> and Higgins<sup>3c</sup> reported the solution of urinary calculi in experimental animals by the administration of vitamin A. Of interest is the experimental observation that administration of vitamin A causes a change in the urinary  $p_H$  from alkaline to an acid reaction. In our experience, by their sole administration neither plain cod liver oil nor halibut liver oil has brought about such a change in this group of patients.

While it is quite plausible that adequate or excessive amounts of vitamin A may permit a return of a damaged epithelial surface to normal and consequently prevent the formation of new stones on this basis, it is not so easily understood how solution of calculi can be effected in human beings through these means. Neither the chemical structure of vitamin A nor any of its

known physiologic properties can conceivably have the remotest effect on a precipitated mass of inert alkaline earth salts, especially when they are so intimately bound up with impervious albuminous material. This mass, which is called a calculus while in the body, is subject to no possible changing influences except those caused by or in the excretory fluid in which it is bathed.

2. *Use of the Acidifying Diet.*—This is based on the fact that precipitation of the salts of alkaline earths take place only in alkaline solution. The converse is also true; i. e., alkaline earth salts in vitro dissolve in acid mediums. With this diet it is believed that the constant excretion of a highly acid urine may cause solution of calculi. The question naturally arises as to the amount or degree of acidity ( $p_H$ ) of the solution required to effect the solution of these salts. Theoretically, the lower the  $p_H$  the more solvent effect the urine will have on certain of the alkaline earth salts. However, in the body there are factors which definitely limit the degree of acidity of the urine. The lowest  $p_H$  obtainable in the urine in our patients was 4.4. At this  $p_H$  uric acid crystals tend to form in the urine and painful crises have been observed.

In studying the range of precipitation of urinary salts according to the  $p_H$  levels of the urine, Higgins<sup>7</sup> has stated that the first evidence of precipitation of the alkaline salts takes place at  $p_H$  6.9. To prevent recurrent stone formation, he believes that the urinary  $p_H$  should be kept below this level. To cause dissolution of calculi with the high vitamin acid ash diet, he believes that the optimum  $p_H$  limits are from 4.9 to 5.2.<sup>1b</sup>

It will be noted that in this series of twenty-seven patients, twenty had a mean  $p_H$  level of 5.2 or lower (table 2). In seven patients the mean  $p_H$  did not reach this level. This inability to reach the desired level of acidity was associated in the main with three causes:

1. Infection with the alkali-producing organisms: *Staphylococcus albus* or *Bacillus proteus*.
2. Poor cooperation of the patient.
3. Poor renal function. Cases of the latter two types were discarded earlier in the treatment and are not included in the series.

Urinary  $p_H$ : The routine method used in the determination of the urinary  $p_H$  was the "universal indicator" covering a range from  $p_H$  4.4 to 8.8. This indicator method was checked frequently by means of a quinhydrone electrode and potentiometer circuit. The latter is the most accurate method available in this  $p_H$  range and can be used with simplicity and speed in the clinic. The volume of urine required is small (from 1 to 5 cc.). The limit of accuracy for the electrical method as used was plus minus 0.03  $p_H$  unit. The disadvantages of the colorimetric method are that:

1. The urine is turbid, which is particularly disturbing in infected urine.
2. The limit of accuracy in the most expert hands is plus minus 0.1  $p_H$  unit.
3. The high color of the urine, generally deep yellow to orange, coincides unfortunately with the color of the indicator in the neighborhood of  $p_H$  5.5.
4. The method requires the use of 10 cc. of fluid for the best results.

At the onset of this work it was immediately realized that the bladder urine may not represent the true  $p_H$  value of the actual urine in the kidney pelvis. This is especially obvious in patients whose kidneys are unin-

**Course in the Hospital.**—On entrance his temperature was 102.4 F., his pulse was 60 and respiration rate 20. His chief complaint was severe headache. Mentally he was clear and answered questions easily and accurately. Speech was normal. There was no paralysis of the cranial nerves. The pupils were rather small but reacted to light and in accommodation. There was well marked photophobia, which made examination of the optic fundi difficult. Both disks, however, appeared to be slightly blurred. There was no definite choking of the optic disks or change in the blood vessels. On examination it was found that his neck was definitely stiffened and it was impossible for him to touch his chin to his chest. The spine also was somewhat stiffened but not tender. There was no paralysis of the arms or legs. The deep reflexes were present and equal. Babinski's sign or other abnormal reaction was not present. Kernig's sign was not present. The spinal fluid was examined at once (table 1). The white blood corpuscles numbered 11,300 per cubic millimeter. Blood culture was negative. On the second day the patient's temperature continued between 101 and 104 F., except for one drop soon after entrance to the hospital, when the temperature was recorded as 97.2 F.

**Neurologic Examination** (by H. R. V.).—The patient, seen on the tenth day, was cooperative, answered questions readily and spoke of going back to his college shortly. Except for some fatigue, the patient was alert. The optic fundi were

Fig. 2 (case 1).—Perivascular infiltration and eccentric foci of gliosis of cerebrum. Eosin methylene stain;  $\times 80$ .

slightly blurred, but there was no choking. Examination of the cranial nerves was negative. Hearing was normal and there was no tenderness over the sinuses or mastoid. The

\* In the tables, day indicates days after the first symptoms, and cells the number of white blood corpuscles per cubic millimeter of cerebrospinal fluid. Where the cells are other than lymphocytes, this fact is noted. The initial pressure is recorded in millimeters of water; the Queckenstedt test was always negative. The total protein, sugar and chlorides are reported in milligrams per hundred cubic centimeters. Fibrin clots, color changes and guinea-pig inoculation results are also noted. The quantitative tests, in cases seen at the Massachusetts General Hospital, were done in the spinal fluid laboratory of that institution by Miss E. F. Grzebiñowska.

† Pellicle formation; 75% lymphocytes; Wassermann test negative.  
‡ Pellicle formation; all lymphocytes; no bacteria in smear or culture; guinea-pig inoculation negative.

neck was not stiff and Kernig's sign was not present. No paralysis was made out. The reflexes were equal and normal throughout. There was no clonus or Babinski sign, no sensory loss or sphincter weakness. Photophobia was present. The patient continued to improve, from the clinical point of view,

although he had to be catheterized three times a day. The white blood corpuscles fell to 8,650 per cubic millimeter from a count on the ninth day of 17,300 per cubic millimeter. The blood sugar was reported as 40 mg. per hundred cubic centimeters. The Hinton test of the blood was negative. A third lumbar puncture showed that the pressure in the spinal fluid was relatively unchanged and that the cells were slightly more numerous than on the second examination. Blood culture in the meantime had shown no growth and a Widal test was negative. During the course of the thirteenth day, in the evening, he appeared about as he had previously. At midnight, however, he became more restless and a considerable amount of mucus developed in his throat. At 5 a. m. November 6 he had a convulsion, and half an hour later a second convulsion was immediately followed by death.

#### POSTMORTEM EXAMINATION

**General Examination.**—The body was examined seven hours after death. All the organs of the body, with the exception of the nervous system, were relatively normal. There was, however, some slight congestion and edema of the lungs, kidneys and spleen, with a mild cystitis. A tuberculous lymph node was found in the mesentery.

**Nervous System.**—There was marked congestion of the tissue of the scalp, and the brain itself appeared edematous. The surfaces were injected and this injection was seen on section throughout the whole brain, including the cerebrum, midbrain, pons, medulla and upper part of the spinal cord.

The meninges were edematous, congested and infiltrated with lymphocytes, chiefly small, with a few large and a few endothelial cells. Cellular infiltration was found extending along the vessels entering the cerebral tissue. The cerebrum showed a localized edema of the cortex just below the surface. In the gray matter a few of the vessels were surrounded by a perivascular infiltration composed of lymphocytes and a few endothelial cells, especially just below the surface of the brain (fig. 1). Perivascular infiltration appeared more intense about the vessels in the white matter, and eccentric foci of gliosis were noted adjacent to these vessels (fig. 2). Occasional vessel walls showed early degenerative changes in the endothelial cells and infiltration of lymphocytes with polymorphonuclear leukocytes in the walls of these vessels. The perivascular infiltration was made up of cells of the lymphocytic series. Other cells resembling microglia and a few large cells four or five times the diameter of the lymphocytes with somewhat acidophilic cytoplasm and eccentric large, indefinite nuclei were observed. Occasionally these cells showed phagocytic activity (fig. 3). The ganglion cells of the cerebrum showed only slight changes. Some of them possessed eccentric nuclei, being otherwise normal. In others the nuclei were beginning to undergo pyknosis, while in still others there was evidence of chromatolysis. Cells in which the nuclear changes were present possessed numerous small vacuoles in their cytoplasm. Still other cells appeared somewhat shrunken. Although no inclusion bodies were noted, cells were seen in which both the nucleus and the cytoplasm took a diffuse dark stain.

In the midbrain the changes noted in the cerebrum were even more evident. Glial nodules were prominent and perivascular hemorrhages were noted. There was well marked evidence of ganglion cell damage similar to that seen in the cerebrum, but in addition, in numerous swollen ganglion cells, cytoplasmic inclusion bodies were seen. In those cells in which the inclusion bodies were few, these bodies were quite rare and of an irregular, rodlike shape. These, surrounded by distinct halos of a dusky red, were usually grouped together at one end of the perikaryon. In other sections of the tissue the inclusion bodies were much smaller and more round. Although colored more intensely than those previously described, they usually lacked a halo. These bodies were situated in a coarse, edematous, yellowish reticulum, which sometimes caused distention and bulging of the cell wall. Surrounding the coarse reticulum a fine bluish reticulum could be seen. In some sections of the midbrain large ganglion cells were observed containing green-

whenever gonadal function is diminished or absent, as in adult hypogonadism,<sup>4</sup> the menopause<sup>5</sup> or castration,<sup>6</sup> there is an excessive excretion of gonadotropic hormone, presumably of pituitary origin. Since the clinical diagnosis of pituitary or other endocrine dyscrasia always is subjected to considerable variation in interpretation, it seemed important to study our cases of cryptorchidism with more objective criteria. We therefore determined, in a semiquantitative manner, the excretion of gonadotropic substance in the urine of our cryptorchid boys, both before and after treatment with gonadotropic substance.

#### PROCEDURE

Three unilateral and ten bilateral cryptorchids between the ages of 5½ and 14½ years were treated with ante-

#### RESULTS AND COMMENT

The results are summarized in the accompanying table. It may be seen that of the three unilateral and ten bilateral cases of cryptorchidism the unilateral (cases 2, 12, 13) and five of the bilateral cases (cases 5, 7, 8, 9, 10) showed no gonadotropic hormone in the urine by our test before treatment, while the other five (cases 1, 3, 4, 6, 11) gave a positive test showing the presence of at least 66 mouse units per liter of urine.

Katzman and Doisy<sup>8</sup> have shown that the urine of normal children contains little or no gonadotropic hormone. We have previously referred to the work of Engle, which shows that in experimentally cryptorchid rats the hypophysis resembles that of the castrated animals. The presence of significant amounts of gonado-

\* Pituitary gonadotropic hormone excreted in urine.

† APL, anterior pituitary-like preparation, Ayerst, McKenna and Harrison derived from the placenta; A-S, antuitrin-S, Parke, Davis & Co. (pregnancy urine extract).

rior pituitary-like substance, from 100 to 150 rat units, three times a week, for a period of from three weeks to four months, the duration depending on the success or failure of treatment. Determinations of gonadotropic hormone were made before the onset, during the course and three months after conclusion of treatment. The method used was Zondek's alcohol precipitation method.<sup>7</sup> According to this method, a minimum of 66 mouse units per liter of urine is demonstrated. A negative reaction, therefore, does not rule out the presence of minimal amounts of the hormone. For practical purposes, however, a negative reaction may be considered as an absence of the hormone, although it is realized that traces of the hormone may be present.

tropic hormone in the urine of cryptorchid children may therefore be compared to the increased excretion of gonadotropic hormone that occurs after castration in man. Since in the castrated person and in cryptorchid boys the gonadotropic hormone is presumably of pituitary origin, it seems logical to conclude that the presence of gonadotropic hormone in the urine of the cryptorchids indicates an active anterior pituitary gland as to gonadotropic function. The appearance of the hormone in the urine may therefore be ascribed to insufficient activity of the gonads which fail to modify the hormone or remove it from the blood. On the other hand the occurrence of cryptorchidism with an absence of gonadotropic hormone in the urine may be interpreted to mean either the presence of a primary pituitary dysfunction or the presence of functionally active

disappeared, and the patient showed no signs of mental abnormality. While the patient was in the hospital, eight examinations of the white blood corpuscles varied from 6,100 to 11,900 per cubic millimeter. Examination of the blood smears was reported as negative. The blood Hinton test was also negative and all the Wassermann tests on the various spinal fluids were negative. A guinea-pig test from the spinal fluid failed to show evidence of tuberculosis. Roentgen examinations of the lung fields were normal and there was no evidence of miliary tuberculosis. Examination of the ears, sinuses, nose and throat was also negative. When the patient was seen again, Jan. 10, 1936, about eighty days after admission to the hospital, he was in perfect health and showed no signs of his recent illness. Spinal fluid examination done at that time is recorded in table 2. A similar examination was made in March 1936. The only abnormal finding was the increased protein in the spinal fluid. The blood, taken in March, was reported on by Dr. Charles

cation,<sup>1</sup> is unchanged. No new signs or symptoms have been discovered. In case 2, however, it will be noted that the lymphocytes may appear in the cerebrospinal fluid in larger numbers than had been suspected previously, reaching a level of nearly 4,000 per cubic millimeter at the height of the disease. Our highest finding in former cases was 790 cells, including 356 polymorphonuclear leukocytes and 79 large lymphocytes in

Armstrong of the National Institute of Health, Washington, D. C., as containing "strong protective antibodies against the virus of lymphocytic choriomeningitis."

CASE 3.—This case is reported through the kindness of Dr. Gerald Blake. Rosalin D. S., a student, aged 18, seen at the hospital Feb. 3, 1936, had been sick for two days with an intense headache. The day before entrance, in addition to the headache, she had a slight stiffness of the neck with Kernig's sign. On entrance to the hospital the cerebrospinal fluid was examined (table 3). The patient at no time seemed very ill and the day after entrance the stiffness of the neck and Kernig's sign were no longer present. In five days she was discharged from the hospital without signs or symptoms. A second examination of the cerebrospinal fluid was not felt to be justified.

COMMENT

The cases here reported illustrate three types of the disease: fatal, prolonged and severe, and transient. In these, as in the cases previously reported, the clinical syndrome varies only in degree, not in character. The description of the disease, given in a previous communi-

case 11, reported in 1934.<sup>1</sup> The protein too, in case 2 of the present series, was higher than previously recorded; 498 mg. per hundred cubic centimeters before any blood had entered the cerebrospinal fluid. These high readings do not appear to justify a change of diagnosis, although the persistence of such a high cell count may well postpone the correct diagnosis, as it did in case 2. The sugar level, falling to 40 mg. per hundred cubic centimeters, has also not been observed before. This finding suggested tuberculous meningitis, until a turn upward the following day was distinctly in favor of meningitis of the benign type (table 2). The protective antibodies also are of interest in view of the work of Armstrong and his colleagues on the virus. Thus, the most severe case with recovery yet observed appears to fit into the same category as those previously described. Case 3 is merely used by way of contrast, to show how mild the disease may be and how transient the symptoms.

Interest centers, however, in case 1, containing the pathologic report. This patient, so far as is known, was the first to come to necropsy. Clinically and serologically the case does not appear to be different from many others that have been reported. The cell count was not higher than is commonly observed;

pressure was much increased, but this has been a not uncommon finding (case 13 in Viets and Watts<sup>1</sup>); the protein, sugar and colloidal gold curve were not abnormal for the disease. The chlorides, however, on the one time that they were done, were lower than we usually see in this disease. The clinical course, moreover, was not unusual, except for the terminal convulsions. The pathologic changes were surprising. Instead of being confined to the meninges, the lesions were

type were reported to be fifty years earlier.<sup>7</sup> Mohr discovered that boys and girls from 10 to 18 years of age in the lower public schools and the gymnasiums of Oslo, Norway, were from 2.52 to 4.88 cm. taller and from 1.97 to 4.31 Kg. heavier in 1930 than similar children were in 1920.<sup>8</sup> A similar report was made from Germany.<sup>9</sup> One of the most striking increases in size was reported for the school children of Leipzig, certain analogous groups of whom showed an increase of 11.6 cm. in height and 11.1 Kg. in weight from 1918 to 1935.<sup>10</sup>

The World War was undoubtedly responsible for the underdevelopment of the school children in 1918, but it is an interesting observation in human biology that children in the aggregate should respond so quickly to more favored circumstances. In discussing the work of Koch, the Berlin correspondent of *THE JOURNAL* said:<sup>11</sup> "This study revealed that the whole period of growth in man has undergone material change. Although the length and weight of man at birth have changed but slightly, the rapidity of growth has increased so that children equal in height children from one and a half to two years older of the prewar period. In both sexes there has been a shortening of the period of maturity of from one and a half to two years."

An interesting study was made at Harvard College several years ago when the records of 1,166 fathers of Harvard students were searched out and compared with the present-day records of their 1,461 sons. The fathers were measured between the years 1875 and 1910 and were found to have a mean height of 68.6 inches (174 cm.). Their sons averaged 70 inches (178 cm.) tall. Similar studies were also made at Wellesley, Vassar, Smith and Mount Holyoke and the college

was conducted by Bowles and published as a monograph.<sup>13</sup> This investigator concluded that stature has been increasing at Harvard for the past eighty years or more and that the mean annual increase has been at the rate of 1 inch every thirty-two years.

The present study was suggested to corroborate the results of others and to contribute some further data

Chart 2.—The weight of freshmen at the University of Cincinnati from 1916 to 1936, arranged by academic years. Men students were weighed stripped, while women were weighed wearing a light weight examining gown. The curve has been smoothed to show the general trend. Yearly averages have been plotted with the same symbols as in chart 1.

Chart 1.—The height of freshmen at the University of Cincinnati from 1916 to 1936, arranged by academic years. Men and women were both measured in their bare feet. The curve has been smoothed to show the general trend. Yearly averages from the table have been plotted by a circle and a dot for men and by a cross for women.

daughters averaged 64.8 inches (164 cm.) in height, which was 1.1 inches (2.79 cm.) taller than their mothers had been while students.<sup>12</sup> The whole study

to this study of widespread interest. Good records of careful physical measurements of students exist in the Students' Health Service of the University of Cincinnati. These records go back to 1916 and contain a history and physical examination for each student. Among other things they show his place of birth, his present legal residence and the place of birth of each of his parents. The geographic distribution of students' homes has remained remarkably constant through the years. The majority of the students are graduates of local high schools or of high schools in Ohio, Kentucky and Indiana. Only a rather small minority come from a greater distance than these three states. There are but few foreign born students among them; most of the young men and women are native born and come of native born parents. The study is thus controlled, to a certain extent at least, geographically.

The students come from middle class homes; there are very few specially privileged ones among them. Many of them are underprivileged and are entirely self supporting. The Harvard study previously mentioned was made on a group that all will admit are a privileged class. Many investigations show that economic status and social position greatly influence growth.<sup>14</sup> The present study bears out these facts, for freshmen at the University of Cincinnati are shorter and lighter than recent Harvard students as reported by Bowles.

CASE 2.—A man, aged 30, had had a right mastoid operation three months prior to consultation. Following the operation a dermatitis developed, which persisted in spite of the efforts of the aurist. The patient became discouraged and, unknown to his aurist, asked for advice. There was marked scaling over the entire posterior surface of the ear, with a fissure in the usual area. The mastoid incision wound had healed. Smears taken from the fissure and also those prepared by pressing out the crusts on glass slides disclosed chains of streptococci. Cultures produced a hemolytic streptococcus. Application of

Fig. 2 (case 2).—Posterior intertriginous scaling and fissuring following mastoid operation.

ammoniated mercury ointment brought about prompt healing (fig. 2).

CASE 3.—A man, aged 43, was seen in June 1933 for "itching ears," which had persisted for some time despite the treatment administered by his aurist. There was no history of otitis media. The patient was given a few treatments with the roentgen rays but no culture was made. Improvement, objectively and subjectively, was marked. In January 1935 the patient returned with an acute dermatitis involving the right concha centering about the right lobe. The left ear was also involved but to a much less degree. All possible irritants were considered. The patient gave up his usual pillow and avoided with great care everything that could conceivably be a factor in the production of such a dermatitis. The canals were red and swollen but there was no indication of furunculosis. There was gradual improvement with local applications, but the condition persisted in both ears and the patient became discouraged. March 27 he reappeared with exacerbation in both canals. The clear serum contained chains of streptococci in the smears, and brain broth cultures repeatedly grew long chains of hemolytic streptococci. Application of 3 per cent ammoniated mercury ointment brought prompt healing, with no recurrence to date. The condition had been undoubtedly, from the beginning, a streptococcic infection of the eczematiforme type which simulated an irritant dermatitis to such a degree that smears and cultures had been neglected and for which only soothing applications had been made for fear of adding further irritation (fig. 3).

CASE 4.—A woman, aged 25, seen April 11, 1935, complained of itching areas, which had been present in both ears for an indefinite time. There was no history of otitis media or of mastoiditis. Various local applications had been made. Examination disclosed crusting and scaling in both vestibules and canals. There was considerable clear serous fluid, in which there were numerous short chains of cocci in the right ear. Brain broth cultures of both ears resulted in cultures of hemolytic streptococci. Ammoniated mercury ointment was prescribed and on April 28 all signs and symptoms had disappeared. There has been no recurrence to date (fig. 4).

CASE 5.—A woman, aged 26, seen in June 1932, complained of itching of the ears for the past year. Various kinds of treatment had been carried on without result. The patient stated that there had been fissures in the labial commissures on

several occasions. Cultures made on agar and on Sabouraud medium resulted in nothing definite. Ammoniated mercury ointment was prescribed on the assumption that a streptococcic infection had been missed. August 4 the ears were apparently healed. The patient was seen again a few times, but in October 1935 she appeared with pain, swelling, erythema and serous crusting in both canals. The erythema extended to the tragus and to the preauricular region. There were chains of cocci and a diphtheroid bacillus in the smears of one ear. Brain broth cultures were positive for hemolytic streptococci. The temperature was 100.3 F. and the white count 18,400. Hospitalization, with hot packs and glycerin and alcohol instillation, resulted in rapid recovery. In all probability this patient had had a streptococcus eczematiforme infection in the canals for three years, but owing to the failure to use proper cultural technique when first seen the organism had not been found.

CASE 6.—A man, aged 60, had suffered considerable discomfort from itching of the ears for the past two years. Various local applications had been made without result. When first seen there was semiserous scaling and crusting in both canals and vestibules. Scrapings were made on glass slides and thoroughly pressed out into thin films with a knife blade. Chains of cocci could be seen in all fields of the preparation. Long chains of hemolytic streptococci were grown in brain broth on two occasions from both ears. Application of ammoniated mercury ointment brought about prompt healing (fig. 5).

CASE 7.—A woman, aged 62, complained of an itching area in the anterior portion of the left auditory meatus, which had been present for three years. The right ear, according to the patient, had not been involved. On examination there was found an area of eczematiforme scaling in the incisura anterior, beneath which could be seen a small fissure. Cultures in brain broth were made on three different occasions in the absence of any treatment, which had been purposely withheld. Short chains of nonhemolytic streptococci were grown in all. This is interesting in view of the observation of Kinnear<sup>4</sup> that the eczematiforme lesions yield anhemolytic streptococci, whereas

Fig. 3 (case 3).—Scaling and crusting of external auditory canal at 4 cavum.

Kinnear found that impetigo invariably yields hemolytic streptococci.

CASE 8.—A man, aged 50, was seen Feb. 17, 1932, for "eczema of the ears" and a patch of serous crusting in the occipital region. The activity in the ears consisted of scaling of the canals and of the vestibules. In the smears there were short chains of cocci but the cultures on blood agar yielded only staphylococci. Both ears were given two roentgen treatments, twice, and an ointment containing salicylic acid and ammoniated mercury was advised for the scalp. February 28 the scalp was

## ACUTE LYMPHOCYTIC MENINGITIS

HENRY R. VIETS, M.D.  
AND  
SHIELDS WARREN, M.D.  
BOSTON

In 1934 Viets and Watts<sup>1</sup> published their third paper on acute aseptic (lymphocytic) meningitis, in which they summarized the literature up to the time of publication, reviewed the five cases that had been observed in 1929, and added details in regard to nine others. It was felt that the syndrome was so well recognized, both in the literature and as the result of their own experience, that the disease should be considered a clinical entity. In the last two years a number of other patients with the same syndrome have been observed and numerous reports have occurred in the literature. In addition to the elucidation of the clinical syndrome, the whole subject has been brought to a focus by the finding of a virus which is probably the etiologic factor in the disease. This virus has been reported by Armstrong and his associates,<sup>2</sup> by Traub,<sup>3</sup> by Rivers and Scott<sup>4</sup> and by Findlay, Alcock and Stern.<sup>5</sup> There appears to be a close connection between the viruses established by these four sets of investigators. Each has been checked against the virus of Armstrong. This paper will not attempt to elucidate the details of the virus identification. It is our object to report further experiences with the disease from the clinical point of view, especially in regard to the variations in its severity, and the pathologic examination of the tissues from one case.

## LITERATURE SINCE 1934

The chief clinical records of the disease will be found in the papers by Scott and Rivers,<sup>4b</sup> who report one case fully observed in a physician, by Findlay, Alcock and Stern<sup>5</sup> whose patients in a London hospital showed a surprising amount of initial paralysis, by López Albo, Feijóo and Goitia,<sup>6</sup> by Cappellini and Pisani,<sup>7</sup> by Dickens,<sup>8</sup> by Hoesch<sup>9</sup> and by Müller and Klan,<sup>10</sup> who differentiate in a table primary from secondary lympho-

cytic meningitis. Nordwall<sup>11</sup> gives a long list of diseases in which lymphocytes appear in the cerebrospinal fluid, including a few cases of primary lymphocytic meningitis. Weismann-Netter<sup>12</sup> had one patient who was comatose and had convulsions; recovery took place. The clinical reports by Terzani,<sup>13</sup> Charleux<sup>14</sup> and others duplicate the already large existing literature. They bring to attention, however, the widespread distribution of the disease. No form of treatment, other than lumbar puncture, has been effective. The disease

Fig. 1 (case 1).—Edema of the meninges and cortex with cellular infiltration along vessels and into cerebral tissue. Eosin methylene stain;  $\times 120$ .

may run a long course, with symptoms of great severity, even when complete recovery ultimately takes place. No deaths have been reported in the literature.

## REPORT OF CASES

**CASE 1.—History.**—Raymond P., aged 20, referred by Dr. F. G. Brigham, entered the hospital Nov. 1, 1934, and died November 7. Seven days before entrance a slight headache developed, which gradually increased in severity, followed by a chill two days later. During the period up to his entrance to the hospital he had several attacks of vomiting. There was no history of tuberculosis in the family. The patient had always been well except for children's diseases and had taken an active part in athletics for a number of years.

necessary in ear infection than in the infections of the hands and feet.<sup>5</sup> Failure to grow streptococci in cases 1, 5 and 8 was due to the use of blood agar only. If blood agar is used, the technic of Sabouraud, which consists in making the inoculation by a long sinuous trail of the loop over the petri dish surface without recharging the wire, should be practiced. At the beginning of the trail only staphylococci will be found, but at the end of the path the staphylococci have thinned out to a degree which allows the delicate streptococci to grow. Haxthausen<sup>2</sup> finds that addition of 0.06 per cent thallium nitrate or 1:100,000 crystal violet to blood agar plates not only will serve to inhibit the staphylococci but also will aid in the determination of the percentage of scales giving cultures, thereby indicating roughly the number of streptococci present. He finds, however, that the staphylococcus inhibitors may also inhibit some strains of delicate streptococci. Crystal violet can be added to liquid cultures in 1:500,000 concentration and successfully inhibit staphy-

Fig. 6 (case 8).—Scaling of cavum and meatus with impetiginous fissuring at incisura intertragica.

lococci. It should be added from a stock solution at the time of inoculation of the tube, because it is decomposed by the high temperature of the autoclave.

The technic of Sabouraud, which consists of drawing up serum in a Wright pipet, sealing off and incubating for seventeen hours, is usually not suitable in the ear infections because of the lack of sufficient serum. When serum is obtainable, the method is very successful and is due to the fact that the streptococcus can survive partial anaerobic conditions, whereas the staphylococcus is an obligatory aerobe. After incubation the tip of the pipet is broken off and the first drop of serum will contain a practically pure culture of streptococci.

A simple and at the same time very successful method of culture is the use of the brain broth glucose medium in tubes at least 12 inches long. Crystal violet may be added if desired. Subcultures on brain broth or blood agar after seventeen hours will be of much aid in finding the more delicate strains. Drawing up a few drops

from the surface of the brain tissue by means of a long Wright pipet and then smearing is the best way of finding the streptococci.

The question arises as to the rôle played by the streptococcus in the etiology of the cases described. Haxthausen<sup>2</sup> was able to find streptococci on normal skin in seven out of ninety-two individuals. Sabouraud<sup>3</sup> answers this as follows: "Dr. Haxthausen would like to establish a sharp distinction between the streptococcus saprophyte and the streptococcus parasite. This distinction seems to me to be purely verbal. There are not two microbes one of which is virulent and the other inoffensive. On the one hand there is an inert organism which merely contaminates a normal skin and on the other an actively multiplying organism which has infected a skin."

Kinnear<sup>6</sup> was able to obtain positive cultures in fifty-one of fifty-two cases of recognized streptococcal diseases of the skin. In fifteen cases of retro-auricular fold lesions of the eczematiform type a nonhemolytic streptococcus was grown in all of them.

The contention of Sabouraud that the streptococci isolated from normal skin can never be considered as saprophytic is given further confirmation by the work of Doid,<sup>7</sup> who divides the reactions of laboratory animals to streptococci into three types: (1) erythema more or less extensive with absence of infiltration; (2) severe inflammatory reaction with infiltration and sharp demarcation of a deep, chronic, necrotic process; (3) rapidly extending cellulitis, with death of the animal within a few days.

With these three types of reactions in mind, the Lévinés and Rabinowitch<sup>8</sup> investigated the pathogenicity of streptococci isolated from the normal skin of fifteen individuals. Of these strains twelve produced a reaction of type 1 and three strains produced a reaction of type 2. The conclusions arrived at by the authors as a result of their investigation are as follows: 1. Streptococci on the normal skin of persons in good health can never be considered as saprophytic. 2. There is a difference in the virulence of streptococci found in various pyodermas from the streptococci found in the normal skin.

#### CONCLUSIONS

Itching and scaling dermatoses in and about the ears may be, in some instances at least, of streptococcal origin.

Failure to obtain positive cultures early in some of the cases of this series was due to faulty technic.

Streptococci on the skin are never to be considered as saprophytic.

I am in complete accord with the observations of Sabouraud.

25 East Washington Street.

#### ABSTRACT OF DISCUSSION

DR. CLINTON W. LANE, St. Louis: Cases of postauricular dermatitis are not all due to the streptococcus. Many cases of similar clinical type accompany a definite seborrhea of the scalp. These are lesions of seborrheic dermatitis which together with the scalp heal with local applications of salicylic acid and sulfur. Postauricular contact dermatitis is indistinguishable clinically from these cases of streptococcal dermatitis. Examples

pigment granules in the perikaryon (fig. 4). In some of these cells the inclusion bodies were crowding out pigment granules; in others they were scattered diffusely throughout (figs. 4 and 5).

In sections of the brain through the internal capsule the reactions previously noted were less intense and no inclusion bodies were found. In other sections of the midbrain these bodies were also not found, even in places in which perivascular reaction and gliosis were marked. In the medulla and at the

perature ranged from 100 to 103 F. but gradually fell off during the second week to normal. There were no changes in the reflexes on the initial examination and the only positive manifestation was a bilateral Kernig sign with some stiffness of the neck. The patient was extremely restless, apprehensive, anxious and at times almost terrified. His lips twitched continuously and he complained of great dryness of the mouth. One examiner thought there was slight weakness of the left side of the soft palate and possibly the right side of the face. There was no difficulty, however, in swallowing or breathing. The patient's condition suggested poliomyelitis of the bulbar type, and this diagnosis was entertained at the beginning of his illness. On the fourth day of his illness he vomited repeatedly and yawned continuously. The fifth day he was somewhat better although he still showed marked anxiety and complained of headache. The right facial paralysis was more definite and there was also paresis of the right soft palate. The reflexes were rather sluggish, but all were present and the plantar responses were normal. Six days after the onset the patient's respirations dropped rather suddenly to 4 per minute, without particular signs of distress and without cyanosis. Yawning was still a prominent symptom. The seventh day the respirations again resumed a rate of 15 per minute and were fairly regular. The next day the respirations became 20 per minute and the patient showed distinct signs of improvement. At this time the cells in the spinal fluid were nearly at their height (table 2). During the next week, except for a slightly infected

Fig. 3 (case 1).—Cell types in perivascular infiltration of the cerebrum. Eosin methylene stain;  $\times 2,000$ .

level of the olivary bodies a few small cellular inclusions without halos were seen in the ganglion cells. In general the changes observed were similar to those found in the cerebrum. In addition, slight neuronophagia was seen. At a slightly lower level in the medulla, perivascular infiltration with nodules of gliosis was observed. The changes in the ganglion cells were slight and no inclusion bodies were noted. In the cerebellum similar perivascular infiltration and gliosis in the white matter was seen, the ganglion cells being little affected and without inclusion bodies. A small section of the upper end of the spinal cord also showed perivascular infiltration and gliosis. The ganglion cells were slightly affected and showed some eccentricity and chromatolysis of the nuclei.

**CASE 2.—History.**—Adam M., aged 18, a student, admitted to the Massachusetts General Hospital Oct. 23, 1935, complained of severe headache of about thirty-six hours' duration. The headache had come on suddenly and was accompanied by a chilly sensation, without actual shaking chills. The patient was unable to sleep the night of the onset and during the night noted some stiffness of his back. About twenty-four hours before entrance to the hospital the patient's headache became very severe and he vomited three times before he entered. The only illness recorded in the past history was tonsillitis prior to tonsillectomy at the age of 8.

**Course in the Hospital.**—The patient was in the hospital from October 23 to November 21. During the first week the tem-

Fig. 4 (case 1).—Large ganglion cell in the midbrain, with inclusion body and pigmented granules. Eosin methylene stain;  $\times 2,350$ .

perature ranged from 100 to 103 F. but gradually fell off during the second week to normal. There were no changes in the reflexes on the initial examination and the only positive manifestation was a bilateral Kernig sign with some stiffness of the neck. The patient was extremely restless, apprehensive, anxious and at times almost terrified. His lips twitched continuously and he complained of great dryness of the mouth. One examiner thought there was slight weakness of the left side of the soft palate and possibly the right side of the face. There was no difficulty, however, in swallowing or breathing. The patient's condition suggested poliomyelitis of the bulbar type, and this diagnosis was entertained at the beginning of his illness. On the fourth day of his illness he vomited repeatedly and yawned continuously. The fifth day he was somewhat better although he still showed marked anxiety and complained of headache. The right facial paralysis was more definite and there was also paresis of the right soft palate. The reflexes were rather sluggish, but all were present and the plantar responses were normal. Six days after the onset the patient's respirations dropped rather suddenly to 4 per minute, without particular signs of distress and without cyanosis. Yawning was still a prominent symptom. The seventh day the respirations again resumed a rate of 15 per minute and were fairly regular. The next day the respirations became 20 per minute and the patient showed distinct signs of improvement. At this time the cells in the spinal fluid were nearly at their height (table 2). During the next week, except for a slightly infected

few weeks ago with a streptococcic fissure at the base of the penis. He had Monilia in the scales of the old lesions, which had practically healed, and a new streptococcic fissure. The two infections can therefore coexist. As to psoriasis back of the ear, in my experience the organism is not present, and usually lesions of psoriasis are found elsewhere, which will help one out. Psoriasis, by the way, can simulate to quite a marked degree the inframammary intertrigo of moniliasis. As regards Dr. Ayers' remark about inadequate proof, one must take it or leave it, for I can't prove it; the patients were all private patients who, I felt, had been mistreated enough and I didn't feel like mistreating them any more. I tried to make it clear that in these cases there was permanent cure as far as I know. Of course I suppose one should use the five-year period as in cancer of the lip, but not enough time has elapsed as yet. Seborrheic dermatitis, as far as I am concerned, does not exist. I don't know what it is, and as to this scaling type of streptococcus, it can be and to all practical purposes is what is understood as seborrheic dermatitis. The *Pityrosporon ovale* preparations are prepared exactly in the same way as are the streptococcus scales, and I have been making them for years on the scalp. *Pityrosporon* is not present in these scales, for I have carefully looked for them. I don't know just what ought to be done about the background. Most of these patients were in excellent health. The background of diabetes, of course, is a factor in Monilia, but not in my experience with streptococcus.

## THE DIAGNOSIS OF TUBAL PREGNANCY

ALBERT MATHIEU, M.D.  
PORTLAND, ORE.

There is probably no more dramatic incident in the life of a physician than that of the textbook type of ruptured tubal pregnancy. This condition, with its typical history of a missed menstrual period, sharp lancinating pain in the lower part of the abdomen followed by dizziness, weakness and faintness, soreness in the abdomen, and bleeding from the vagina, represents only a small percentage of all the cases of tubal pregnancy. The others, not typical, are at times very difficult to diagnose. There are patients with symptoms and complaints so minor or so bizarre that the physician may actually wonder whether or not there is anything wrong at all. There is no doubt that many cases go undiagnosed and that the effects go unnoticed. Witness as proof of this the number of lithopedions that have been found. With the exception of rupture of a graafian follicle or a corpus luteum with hemorrhage, no other pelvic disorder is so easily misinterpreted.

Collected statistics are usually gathered on the basis of tubal pregnancies correctly diagnosed. With this method of figuring, some clinics can boast of correct diagnoses of from 50 to 70 per cent of their cases. However, if these statistics took into account the number of cases diagnosed as tubal pregnancies which proved not to be such, the percentage of correct diagnoses would fall appreciably. One fact is undeniable: the diagnosis cannot be made unless the physician has the condition in mind. He must remember that any vaginal bleeding in the child-bearing age following a missed period might possibly mean an ectopic pregnancy.

This discussion will be limited almost entirely to the diagnosis of tubal pregnancy and will stress some of the more or less unusual diagnostic methods under the following headings: pelvic examination, pain, pregnancy tests, decidua, needling of the posterior culdesac, Cullen's sign, urobilinogen and icterus index tests, sedimentation test and hysterosalpingography.

The pathologic condition found explains quite accurately the symptoms seen by the physician. In other words, the size of the pregnancy, its location in the tube, whether it is rupturing or has ruptured, and whether it is aborting from the distal end or has aborted leaves its characteristic mark in the clinical picture.

### PELVIC EXAMINATION

One would think that pelvic examination would clear up the whole matter, but often this examination reveals nothing of importance. If there is a palpable mass it may vary in size from that of a normal ovary to one that fills the entire pelvis. This mass may be tense, fluctuant or boggy. Frequently there is no mass palpable. The best positive evidence by pelvic examination is obtained by palpating the cervix and uterine body. The cervix may be soft or patent, the body of the uterus is usually enlarged, and movement of the cervix or of the fundus causes pain. Usually generalized pelvic pain is elicited in bimanual examination.

### PAIN

There are eight types of pain connected with this condition, all explainable on a pathologic basis:

1. Acute lancinating pain coincident with rupture of the tube.
2. Dull, constant pain associated with stretching and slow tearing of the tube before rupture.
3. Crampy, almost constant pain caused by peristalsis of the tube and dilatation of the distal end of the tube during a tubal abortion.
4. Soreness and tenderness of the entire abdomen caused by irritation of the peritoneum from the escaped blood.
5. Phrenic or shoulder pain produced when the blood gets high in the abdominal cavity, under the diaphragm, and irritates the phrenic nerve endings (this pain is felt on either side or both sides of the neck).
6. Pain elicited by the deep muscle resistance that results when the palpating fingers sink deeply enough to cause pressure on the parietal peritoneum.

Fig. 1.—Tubal pregnancy aborting from the left tube. Note the peculiar hazy filling of the entire left tube and filling defects in the uterine cavity, probably due to decidua.

When there is free blood in the abdominal cavity, palpation of the anterior abdominal wall is almost pathognomonic. In such a patient the abdomen is usually not distended. There is generalized pain or soreness over the entire abdomen and with fairly light palpation the fingers will sink part way into the abdominal wall without resistance, only to be met by a rather doughy resistance as the fingers sink deeper. This

widespread throughout the central nervous system, and encephalitis, as well as meningitis, was well marked. With so evident an encephalitis it might well be questioned whether one should classify this case as acute lymphocytic meningitis. Clinically the patient conformed to the accepted diagnosis, and the appearances in the cerebrospinal fluid were consistent with what little is known about the disease. Further studies in the pathology of this syndrome are needed. On the basis of one case, it is justifiable only to set down the observations, without drawing definite conclusions regarding them. The nervous tissue reaction was a severe one, although the pathologic appearance did not preclude recovery.

#### CONCLUSIONS

Acute lymphocytic meningitis, now classed as a specific virus disease, shows a wide variety of clinical manifestations. The disease may be transient, severe and prolonged, or even fatal. Examples of all three types are reported, with a detailed examination of the cerebral tissue from the fatal case. Based on this single report, the disease in its most severe form is an encephalitis as well as a meningitis. With the recovery rate nearly 100 per cent, it must be assumed, however, that the degree of encephalitis in the majority of cases reported is not profound, and therefore the clinical designation of acute lymphocytic meningitis is still justified.

### STREPTOCOCCIC DERMATOSES OF THE EARS

JAMES H. MITCHELL, M.D.

CHICAGO

Pruritic and scaling dermatoses of the ears are frequently encountered by both the aurist and the dermatologist. Various terms, such as "eczema" and "seborrheic dermatitis," are applied to them. Retro-auricular intertrigos, with serous crusting, scaling and fissuring, are not infrequently seen and are recognized by many as due to a streptococcus. Itching and scaling of the cavum, auditory meatus and canal, however, are not so readily accepted as being of streptococcal origin, particularly in America. In this country the tendency seems to be to regard itching of the canals as "eczema" or as a mycosis, judging from the replies to queries in both the medical and the lay press, and from what patients say they have been told by various physicians. It is true that an infection by *Aspergillus niger* occurs in the canals, but in my experience that infection is extremely rare and is readily recognized; clinically by the appearance of the plug in the canal and microscopically by finding the fungi in the mass.

My object in this paper is to focus attention on the rôle played by streptococci in the production of dermatoses of the ear, and to aid, if possible, in the differential diagnosis of aural lesions by describing the clinical manifestations of the streptococcal infections and the laboratory procedures necessary to establish the diagnosis.

As long ago as 1897 and 1900, Sabouraud described streptococcal retro-auricular intertrigo and scaling plaques extending into the scalp. The scaling plaques

may produce alopecia resembling that of ringworm to such a degree that only by microscopic examination can the diagnosis be determined. An excellent example of this type of case is to be found on page 150 of *Pyodermites et eczémas*, by Sabouraud.<sup>1</sup> Of this manifestation of the disorder he says "It was confused and is still confused with impetiginous eczema (?) or even called seborrheic eczema, by a flagrant impropriety of terms." This subacute impetigo, according to Sabouraud, is the *porrigo scabida* or *impetigo scabida* of Alibert, depending on the stage of evolution of the disorder.

For this scaling type of lesion Haxthausen<sup>2</sup> has proposed the term *pityriasis streptogène*. This term, however, Sabouraud<sup>3</sup> says is not a happy one and that all epidermic streptococcal infections which have not already been given a definite classification should be called *streptococcides eczématiformes*.

The retro-auricular intertrigo is so well recognized that I wish to call attention especially to the streptococcal *eczématiformes* of the cavum and canal and to report cases in which the two conditions have coexisted or have been preceded one by the other. A few cases presenting the conditions mentioned will be presented in detail:

CASE 1.—A woman, aged 20, was seen in January 1931 with a scaling disorder about the canal and cavum of the left ear. There was similar activity on the posterior surface, in addition to which there was a deep and tender fissure. On both surfaces of the right ear there was similar but much less activity. In the scalp there was a diffuse *pityriasis steatoides*. The patient stated that her left ear had had a discharge several months before the onset of the auricular dermatoses and that she had had a similar discharging of the left ear in childhood. Cultures were made of both ears on blood agar which yielded only staphylococci and on Sabouraud medium which produced the same organism. The patient was given some radiotherapy for the ears together with a 10 per cent naftalan ointment. For the scalp she was given an ointment containing salicylic acid and ammoniated mercury. She made rapid improvement and on the fifth visit, March 2, the ears were apparently healed. She was next seen November 4, with weeping, crusting and fissuring back of the ears and marked scaling in the canals. She had been wearing white gold bows to her glasses for several months and later a brownish composition which, on inquiry, was found to be free from nickel. Careful cultures taken from the fissures, canals and tonsils gave a hemolytic streptococcus. After removal of the tonsils, in which there was a chronic hemolytic streptococcus infection, and local application of ammoniated mercury ointment, the infection cleared and remained so. The smears and culture slides were lost and no photographic record was made (fig. 1).

Fig. 1 (case 1).—Posterior intertriginous scaling and fissuring simulating seborrheic dermatitis. The right ear was similarly affected. Complete healing occurred after application of ammoniated mercury and removal of infected tonsils.

## CULLEN'S SIGN

The sign described by Cullen is the presence of an area of ecchymosis in the tissues of the umbilicus. There must of necessity be not only an actual hernia but also some break in the integrity of the peritoneum at this site so that the blood can actually reach the subcutaneous tissues. One can easily see that with these requirements the sign must be exceedingly rare. However, once this thought of Cullen's sign was the actual pivotal point in the diagnosis in a very sick patient. This patient appeared at the hospital with the lower por-

Fig. 4.—Hysterosalpingogram showing peculiar abrupt rounded ending in middle of right tube just proximal to tubal pregnancy.

tion of the abdomen entirely filled with what appeared to be a huge pelvic abscess. The intern was able to elicit from her a very fine history, which seemed to confirm the diagnosis of salpingitis with pelvic abscess. On examining the patient, almost the first thing I noticed was an ecchymotic area in an incisional scar in the lower portion of the abdominal wall with definite evidence of a very small hernia in the scar. This evidence (the ecchymosis in a small hernia in the scar) I took to be Cullen's sign and made a diagnosis of ruptured ectopic pregnancy. I asked the intern to take another history with the thought of ruptured ectopic pregnancy in mind (he had not thought of ectopic pregnancy at the time he took the history). He presented me later with the history of a typical textbook picture of a ruptured ectopic pregnancy which contained these words: "She was well on Monday and worked. She worked on Tuesday. She worked on Wednesday. But on Wednesday evening she suffered an acute lancinating pain in the lower abdomen and soon after this she fainted." Operation revealed the mass in the lower part of the abdomen to consist of clotted blood which came from the rupture of a rather large tubal pregnancy. The abdominal incision was made through the former scar and a small hernia was found approximately 0.5 cm. in diameter with a tiny piece of omentum projected through a defect in the peritoneum. The blood had seeped along this piece of omentum and had gotten into the subcutaneous tissues. An added note of interest is contained in a letter from Cullen, who said he had never seen or heard of such a variant of the sign.

## UROBILINOGEN AND ICTERUS INDEX TESTS

I have been unable to find in any textbook on gynecology a reference to the urobilinogen or the icterus index tests as aids in the diagnosis of ruptured ectopic pregnancy. However, these tests are well described in books on laboratory diagnosis,<sup>1</sup> with the information that they are of value in determining the presence of a hematoma or of blood in the process of absorption. On more than one occasion in my experience these tests proved to be the key-point in reaching a correct diagnosis. I mentioned them in a paper on pregnancy tests some years ago.<sup>2</sup> I know of no specific test for ectopic pregnancy per se, but these tests are good for determining the presence of a hematoma which might point to ruptured ectopic pregnancy.

## SEDIMENTATION TEST

The sedimentation rate cannot be relied on in the diagnosis of ectopic pregnancy except in a negative way. There is either no change in the rate of sedimentation of the red cells or only a slight increase in this rate. Of course, days after a rupture, when an encysted hematoma is present, there might be some appreciable increase in the rate. But the chief value of the test in this condition is in its use as a differential diagnostic procedure in ectopic pregnancy, salpingectomy and pelvic abscess. In both salpingitis and pelvic abscess there is a marked increase in the sedimentation rate which can be used for its differential value. In other words, a high sedimentation rate usually rules out ectopic pregnancy, while a low rate usually rules out pelvic abscess or acute salpingitis. To depend on this test for anything more is wrong.

## HYSTEROSALPINGOGRAPHY

I have used hysterosalpingography in several cases as an aid in diagnosis and have obtained practically 100 per cent correct diagnoses. I have been able to visualize beautifully the abortion of the tubes (figs. 1.

Fig. 5.—Showing abrupt rounded ending of left tube just proximal to tubal pregnancy. All cases presented in the illustrations were diagnosed before operation and proved at operation.

2 and 3) and to establish what seems to be a pathognomonic x-ray sign (figs. 4 and 5) for a tubal pregnancy in the midportion of the tube. In cases of tubal pregnancy aborting from the distal end of the tube, the injected oil enters all the crevices between the aborting pregnancy and the walls of the distal ends of the tubes.

2. Mathieu, Albert: *Pregnancy Tests*, *M. Sertoli* 37:623 (Nov) 1929.

clear and the ears were much less itchy but still scaly. The patient was not seen again until May 1, 1936, at which time scaling in the canals and cavae of both ears was marked. On the left helix was an area of a subacute impetiginous type of infection. At the incisura intertragica of the right ear was a similar area with serous crusting, beneath which was a fissure. Furfuraceous scales could be easily gathered on a curet from the cavum and canal. These scales, when pressed out on a glass slide and stained with methylene blue, disclosed short chains of cocci in all fields. Cultures of the scales in brain broth, with

no attempt at selection of material, produced short chains of streptococci in all tubes. Examination of ten hour cultures disclosed short chains of streptococci only. After twenty-four hours small groups of staphylococci were to be seen (fig. 6).

The patient was given 3 per cent ammoniated mercury ointment, with prompt relief of subjective symptoms and marked improvement in the clinical appearance of the lesions.

Retro-auricular intertrigo may be associated with intertriginous fissures in other parts of the body, illustrated by the following case:

Fig. 4 (case 4).—Mild scaling in the cavum with marked itching.

1933 with a severe retro-auricular intertrigo and fissuring of the right ear. She also had inframammary intertrigo and fissures and a similar involvement of the umbilicus. Fungi were absent, but both brain broth and blood agar cultures produced short chains of hemolytic streptococci from all of the lesions. The patient, the only clinic one in this group, disappeared and her present condition is not known.

The association of chronic otitis media, perforated drum membrane and "running ear" with the streptococcide eczématiforme of Sabouraud is illustrated by the following case:

CASE 10.—A man, aged 48, who was referred for treatment for lupus erythematosus of the chronic fixed type on the cheeks was found to have marked scaling and itching of the right canal and concha. The discharging ear had been present for such a long time that the patient was not at all concerned. In the clear serous fluid and in the scales, hemolytic streptococci were found both in smears and in cultures. As the patient was nominally under the care of an otolaryngologist, no treatment was advised. Improvement of the lupus erythematosus under sodium gold thiosulfate was rapid and the patient ceased his visits. He has not been seen for several years.

The clinical manifestations of retro-auricular intertrigo are fairly definite. If the lesion is seen shortly after onset there is a fissure deep in the retro-auricular fold, and the posterior surface of the ear is bright red and covered with clear serum. Quickly the weeping subsides and is succeeded by a thin white squamelike crust. By extension the lesion may involve the scalp, developing the so-called seborrheic dermatitis, which Sabouraud terms *impétigo en nappes* and which he says is the *impétigo scabida* of Alibert. The retro-auricular lesions may involve one or both ears, but if

both ears are affected they are rarely involved to the same degree at a given time. The posterior lesion may coexist or alternate with the canal and cavum infections.

The lesions of the concha may or may not be preceded by "running ears." The patient gives a history of gradual onset of itching in the canals, which in time may be very troublesome. Only one or both the ears may be affected but again, as with the retro-auricular lesions, the activity is rarely bilaterally symmetrical. The canals may be dull red and somewhat lessened in caliber or there may be only the squamelike crust rather firmly adherent to the skin of the canals, meatus, cavum and even in the fossa triangularis. Fissures similar to those seen in the nares may be found at the incisura anterior (case 7) or at the incisura intertragica (case 8). These fissures may be concealed by yellowish, firmly adherent crusts. Removal of the crust is painful and discloses beneath it a bright red moist fissure with a minute amount of clear serum in which streptococci are easily demonstrated.

The diagnosis must be verified by laboratory methods adapted to the purpose. The presence or absence of fungi can be readily determined by microscopic examination of the scales in the usual solutions of potassium or sodium hydroxide. Sensitization to nickel can be determined by the application of the patch test. Other irritants should be searched for in the history and eliminated if found.

Microscopic demonstration of the streptococci in the serum from the fissures and in the squamelike crusts is not at all difficult. If serum is found, smearing and staining with methylene blue will disclose the presence of streptococci. If only the squamous scales are availa-

Fig. 5 (case 6).—Scaly and itchy lesions in the canal and about the meatus.

ble, they should be carefully and patiently pressed out on a slide with a thin blade. Eventually the material can be finely divided and made to adhere to the slide. This is then fixed with heat and stained with methylene blue. The preparations do not lend themselves well to photography because of the thickness and unevenness of the individual masses. Nevertheless it is possible to obtain fairly good photomicrographs.

Cultures can be uniformly obtained successfully only by special methods. The special methods are even more

results in cases involving mainly the skin and subcutaneous tissues. These cases appear serious because of the extensive blebs, black discoloration, edema and pain. However, the only tissue seriously injured in these cases is the epithelium, which heals with simple dressings. Therapeutic efficacy must be judged by the less common cases of white, stiff, cold fingers or toes

Fig. 3 (A. A.).—January 1936, loss of little finger.

which go on to formation of indolent ulcers or bone necrosis.

It has long been assumed that frost-bite is a peripheral vascular occlusion that is spastic in the early stages and thrombotic in later stages. This assumption requires reexamination. Cold first causes a sensory paralysis—an anesthesia—and it is because of this anesthesia that the patient is unaware of the condition and exposure is continued, and the frost-bite progresses to the danger point. Clinically, it seems to me, the ulcers of frost-bite resemble trophic ulcers more closely than the lesions of vascular disease. The dry necrosis of bone, without any infection, suggests some etiology other than vascular disease. One must inquire whether sensory nerve paralysis or direct tissue injury is not a more important factor in serious frost-bite than is usually imagined. Progress in the therapy of frost-bite must await a more detailed study of the pathologic effects of cold.

#### PREVENTION

The poor results of treatment emphasized the need of prevention. A man with diabetes or advanced arteriosclerosis should not be permitted to work outdoors in freezing weather. For him, frost-bite is an extraordinary risk.

In the previous communication I suggested that workers be given time off every two hours to warm up.

Fig. 4 (W. B.).—January 1936, no amputation; loss of flexion in distal joints of all four fingers resulting in complete loss of grasping power.

A more detailed analysis of the 556 cases occurring since then demonstrates that 65 per cent of cases occur in the first two hours of exposure and 90 per cent in the first three hours. Therefore any such method of prevention must prove futile.

Protection by adequate clothing has produced a dramatic decrease in the incidence of frost-bite. In 1934-

1935 most of the men wore no ear protectors; the temporary laborers wore cotton or shoddy wool gloves, bought for from 10 to 40 cents, which gave a minimum of insulation against cold. Foot protection was equally inadequate (fig. 6). With better clothing the frost-bite cases dropped from an average of 393 for the winters of 1933-1935 to 186 in 1935-1936 (fig. 7), although the number of men exposed to frost-bite weather was greatest in the last year.

Regular employees were protected against frost-bite by orders and instructions issued in the autumn of 1934. Most of the temporary snow laborers were given the necessary clothing in the autumn of 1935 (fig. 8). Because of the difference in method and of time we

Fig. 5 (P. H.).—February 1936, loss of all five toes and part of foot.

have a clear basis for the comparison of the effect of these measures on the incidence of frost-bite. There was a sharp decrease in number among regular employees in 1934-1935 after precautions were taken, although in that winter there was an increase among

Fig. 6.—Temporary laborers in 1933-1934. No ear flaps and inadequate protection for hands and feet. Two regular employees (in uniform), both without ear flaps, one without gloves. (Photograph by Department of Sanitation.)

temporary laborers (fig. 7). The following year (1935-1936) adequate protection was provided for temporary laborers and there was a sharp decrease in the number of frost-bites among these men in that winter in spite of the fact that more men were exposed to frost-bite weather than in any preceding winter.

**Ears.**—Late in 1934 the commissioner of sanitation issued orders that all regular employees must have ear flaps on their uniform caps ready for use in case of cold. From the 1933-1934 record of seventy-five cases of frost-bitten ears among regular employees, the number dropped to four in 1934-1935. In the same winter the number among the temporary laborers showed a

of this are the patients sensitive to nickel in the ear pieces of their glasses and the women sensitive to hair dye and to toilet water applied behind the ears. Such eruptions disappear with the removal of the cause and the application of soothing medications. The interesting point is the manner by which the streptococcus invades these regions. In an ascending irritation of the auditory canal that follows purulent otitis media and rupture of the drum there is no question about the origin of the infection. The descending infection is more difficult to fathom. Cerumen is irritating at times, and various implements are used to remove it. Hair pins, common steel pins and other such agents may traumatize the mucous membrane and set up a streptococcal infection. Postauricular irritation may also be due to trauma. The patient with dandruff usually has pruritus about the ears four or five days following a shampoo. The scratching and rubbing finger nail may deposit the streptococcus. I agree with Dr. Mitchell that there is such a disease as streptococcal dermatitis of the ears. In some cases it is a primary infection but in many it is secondary to some other condition. I still do not feel that a diagnosis of seborrheic dermatitis is always incorrect.

Dr. S. W. BECKER, Chicago: Dr. Mitchell is to be congratulated on his various contributions on the rôle of the streptococcus in inflammatory diseases of the skin. The present tendency is an enthusiasm for fungous infections, and the aurists with whom I am associated are inclined to call all these conditions due to fungi or yeasts. Some years ago Dr. Ritchie and I obtained cultures of cryptococci from these lesions, but we were never able to prove by the number of cryptococci or by inoculation experiments that they were causative. There are certain streptococcal eczemas, as we call them, which will not respond to the ordinary applications. The chief feature of these conditions is often the marked erythema and the enormous exudation. In many cases, when there is at all a suspicion that the streptococcus may be causative, it is our custom to supply the patient with some sulfonated bitumen or tar preparation for use at night and ammoniated mercury to use in the daytime. In that way the condition is relieved if it happens to be a seborrheic dermatitis, and it is also relieved if it happens to be streptococcal.

Dr. ANTHONY C. CIPOLLARO, New York: Dr. Mitchell has clarified the etiology of many conditions involving the ear canals and the postauricular regions. I have had great difficulty in differentiating the different diseases that occur in these locations. I thank him for bringing to attention the fact that streptococci are capable of producing these scaly and itching dermatoses of the external auditory canals. Within the past two or three years I have been particularly interested in unusual forms of psoriasis, and to my surprise I have been finding that a great many of these eczemas involving the postauricular areas which clinically resemble intertrigo have turned out to be psoriasis. Many intertrigo-like eruptions involving the postauricular areas, axillae, submammary regions, umbilicus and inguinal areas which were recalcitrant to therapy have been proved by biopsy to be cases of psoriasis. I am glad to know that many of these conditions can also be caused by a streptococcal infection.

Dr. SAMUEL AYRES JR., Los Angeles: I can't feel that adequate proof has been presented that the streptococcus found is the cause of the skin lesion. The mere fact that a special culture medium was used and the streptococcus found does not prove that this organism any more than the staphylococcus is the cause of the lesion in question. It would be interesting if Dr. Mitchell would make intradermal tests of all the organisms that could be found by using different types of culture medium and see which particular organisms the patient was sensitive to. I would also like to ask him how permanent the results of treatment have been following the use of ammoniated mercury. My impression is that I have employed that drug but that there has been a tendency to recurrence. I have felt that many of these cases are a type of seborrheic dermatitis, since they seem to be associated with the characteristic lesions of the scalp, and it is quite possible that, if proper culture mediums were employed, *Pityrosporum ovale* also would be found in these ear lesions. I should like to mention also that such lesions within the ear canal can at times be due to allergic manifestations. I recall one particular instance in a woman who

had had a history of allergic reactions of various sorts, including eczema from childhood on, who developed severe contact dermatitis from an ointment containing procaine hydrochloride. This patient was later operated on for tonsillectomy and died on the operating table from the injection of procaine, apparently an extremely sensitive individual with varying types of sensitivity.

Dr. D. TRUETT GANDY, Houston, Texas: Dr. Mitchell is concerned in his discussion with streptococcal dermatitis chiefly in the region of the ears. I think it should be pointed out that, according to the French, who have written a good deal on this subject, this form of infection frequently involves the other folds of the body in addition to the postauricular fold. Sabouraud has said of the streptococcus that "it loves the folds," and that is certainly true of this condition. This infection may vary from a tiny lesion behind the ear to a more or less generalized involvement, and in the latter case the obvious predilection for the folds is a striking feature and constitutes a noteworthy point of difference from impetigo. I wonder whether some of the impetigos of the major folds of the body, such as in the submammary region in the slide just shown by Dr. Mitchell, heretofore regarded as yeast infections, may not be at least partly streptococcal in origin. It should be reiterated that streptococcal dermatitis is not an eczema and that it has no right to be called seborrheic. It seems plausible that this concept of streptococcal dermatitis as a separate and distinct disease may be a step forward in sorting out the "rubbish heap" of seborrhea, in the same way that the splitting off of the fungus infections reduced the size of the eczema group.

Dr. MOSES SCHOLTZ, Los Angeles: Dr. Mitchell has confirmed something that the clinician has been suspecting for a long time. Whenever a clinician sees a marked marginated lesion with exudation he suspects streptococci. However bacteriology alone will not solve these cases completely. Infection in these cases is entirely secondary, and I am rather surprised that not one of the discussers has emphasized the systemic background of these cases. If the clinical behavior of these cases is compared with impetigo, it will be seen that impetigo clears up but does not recur; but these cases recur time and again. It shows that there is a systemic background that breeds there a reinfection, a recurrence. Also in these cases one sees a considerable mixture of the morphologic picture, which may look one day like eczema, another day like seborrheic dermatitis. I am obliged to disagree with the last speaker. It will be a great step in advance if these morphologic units are not considered separately. Excuse me for emphasizing my dynamic point of view, which conceives dermatoses as a biologic reaction which can change the morphologic pattern. The solution of these cases is not in the laboratory but in the clinical and the etiologic study of the case, and any one who neglects the systemic and dietetic side of these cases will have more trouble than those who pay attention to the systemic angle.

Dr. JAMES HERBERT MITCHELL, Chicago: I tried to make it clear in the hasty presentation that I was dealing with cases in which I was not able to determine some other causative factor. As regards nickel, hair dye, resorcinol and various other irritants, I have seen all of those, and such cases are familiar to all dermatologists. I assumed at first in one of the cases I spoke of that it might be a dermatitis of that sort. I even had the patient isolate himself from his wife, with the thought that he might be sensitized to her hair or to her cosmetics. We went to great extremes in that particular instance. As regards the origin of the streptococcus in the ear, there is an old Chinese adage: "Never pick your nose or your ear with anything but your elbow." I tried to make clear that the presence of otitis media made it perfectly simple to account for the streptococcal origin of the dermatosis. I am interested in the fungi, and some of the Chicago men know of the rather extensive collection of *Monilia* pictures and the work that I have done in that field. *Monilia intertrigo* is clinically different and the streptococcus is not present. The maceration of the *Monilia intertrigo* is quite extensive and is usually symmetrical. As regards the other folds, streptococcal intertrigo may occur in all the folds. I have a patient now who has had *Monilia infection* in the crotch. He came in a

present, there should be little difficulty in diagnosis. Unfortunately, the atypical cases are in the majority. This study is based on 153 cases of ectopic pregnancy: ninety-eight seen in the department of obstetrics and gynecology of the State University of Iowa College of Medicine, sixty-two of which have been reported by Brown,<sup>3</sup> and fifty-five cases in which one of us (E. v. G.) operated in private practice and at the Second Gynecologic Clinic in Vienna, Austria.

Fig. 1.—Correct diagnosis was made with persistent, brown, bloody discharge as the only symptom.

Operation immediately after the condition was recognized resulted in a mortality of two (1.96 per cent). The only death among the patients seen at Iowa City and reported by Brown was caused by hemorrhage into the incision. Two of the patients operated on in Vienna succumbed, one to a pulmonary embolism on the fourth postoperative day and one to an embolic obstruction of the superior mesenteric artery on the third postoperative day. In none of these cases was death caused by the operation itself or by its immediate performance.

Repetition of the well known phases of the subject will be omitted, and the discussion will be limited to a few points that may help in the diagnosis of many atypical cases of ectopic pregnancy.

A thorough previous history is of tremendous importance. If pelvic inflammation or gestational disturbances appear in the story of a woman with vaginal bleeding, suspicion should be aroused.

TABLE 1.—Gestational History (Ninety-Five Cases with Adequate Records)

Pregnancy Preceding Ectopic Pregnancy	Number of Cases	Per Cent
Primary sterility.....	18	18.8
Ectopic pregnancy.....	5	5.3
Abortion.....	25	26.3
Delivery at term.....	47	49.5
followed by a sterile period of from 3 to 16 years in 23 cases		

Of this series, 33 per cent of ninety-five cases gave evidence of previous pelvic inflammation of some sort. In addition, some similar pathologic condition could be inferred from the record of previous pregnancies. In 19 per cent the ectopic pregnancy followed a period of primary sterility, in 26 per cent the pregnancy preceding the ectopic pregnancy had resulted in an abortion, while 5 per cent of the patients had experienced a previous ectopic pregnancy. The ectopic pregnancy followed a delivery at term in only half of the cases but followed it at a markedly long interval. In twenty-three instances there had been no pregnancy for a period of from three to sixteen years. Although contraception is a factor, this delay suggests secondary sterility.

In none of these cases was the patient herself conscious of pelvic disease. However, inflammation could

be suspected wherever an ectopic pregnancy or a previous abortion had occurred. Underdevelopment may have caused part of the primary sterility and favored the ectopic nidation but, on the whole, the presence of sterility and, particularly, secondary sterility suggests inflammation.

The importance of previous miscarriage is well illustrated by a report of Bamberger.<sup>4</sup> Among his 150 ectopic pregnancies, sixty-three occurred following criminal abortions.

The history of bleeding is an essential point. There is no tubal abortion or rupture without uterine bleeding. If the patient starts bleeding after missing at least one menstruation and the onset is accompanied by localized abdominal pain, with or without nausea and dizziness, the diagnosis is fairly obvious. Unfortunately, this happens in less than 40 per cent.

TABLE 2.—History of Bleeding (Ninety-Two Cases with Reliable Data)

Irregular Bleeding for from Three to Ten Months	Amenorrhea: Onset of Bleeding from a Few Days to Three Months Following the First Missed Menstruation	No Previous Amenorrhea: Onset of Bleeding:	
		During Inter-menstruum	Presumably at a Normal Period
8 9%	33 35%	21, 23%	23, 25%
		40, 53%	

As table 2 shows, in 9 per cent irregular bleeding over a period of several months barred definite conclusions. In 38 per cent the bleeding followed amenorrhea as in the classic picture, but 53 per cent showed absolutely no previous menstrual disturbances. The bleeding started either during the intermenstruum or at the expected time, presumably as a normal period, but was unduly prolonged.

The latter type of bleeding is very misleading, especially if there are no local symptoms. Such an early stage of pregnancy often causes little or no perceptible discomfort. There is no doubt that many pregnancies, both intra-uterine and extra-uterine, terminate spontaneously, without any symptoms beyond a more than usually profuse menstruation.

Table 2 indicates quite clearly that in more than 60 per cent of these cases the menstrual history does not show the typical disturbance. Obviously this is the most important cause of mistaken diagnosis of ectopic pregnancy and it is not merely a coincidence that nine out of the fifteen diagnostic errors in our own material included this type of misleading menstrual history.

Fig. 2.—Properly diagnosed ectopic pregnancy, which, because of the absence of retro-uterine hematocoele, could have been mistaken for a pyosalpinx.

Observation of the bleeding itself offers definite clues to its cause.

At the onset there may be copious bleeding with the expulsion of clots and tissue. As this is equally characteristic of intra-uterine miscarriage and only histologic examination will determine the nature of the material, confusion is understandable. While the blood in uterine abortion, dark or light, remains red, in ectopic pregnancy the discharge gradually assumes a dirty

J. Brown, T.: Ectopic Pregnancy. *Am. J. Surg.* 27: 89-84 (Jan.) 1935.

4. Bamberger, E.: Beobachtungen an 150 Extra-uterin Schwangerschaften. *Zentrabl. f. Gyn.* 47: 397, 1924.

tenderness is quite unlike that of the acute firm resistance and tenderness one finds in acute appendicitis with peritoneal involvement.

7. Pain produced by moving the cervix or the fundus.

8. Generalized pelvic tenderness and pain produced by the palpating fingers.

Here again is corroborative proof that the pathologic condition leaves its mark in the clinical picture. In

Fig. 2.—Tubal abortion as shown in hysterosalpingogram (fig. 1). The sketch of the left tube was made from the posterior aspect of the pathologic specimen.

many cases this knowledge of the character and location of the pain will aid in arriving at a solution of the problem.

#### PREGNANCY TESTS

The Aschheim-Zondek test, or its modification the Friedman test, has been a disappointment to many in the diagnosing of ectopic pregnancy, owing to a misconception of what the test really means. A positive test means that there is living chorionic tissue present. Hence the test can be positive even when the fetus is dead. A negative test merely means that there is no living chorionic tissue present. Therefore the test will not exclude the diagnosis of ectopic pregnancy.

#### DECIDUA

It is a physiologic fact that wherever a pregnancy exists—be it in the uterus, the tube, the ovary or the abdomen—decidua is formed in the uterus, and when the fetus dies or when the pregnancy is disrupted the decidual lining of the uterine cavity is cast off and bleeding takes place. This, in all but a few rare cases, is the cause of the uterine bleeding. Probably the only time that blood regurgitates from the tube into the uterus is in the rare condition of interstitial pregnancy. On two or three occasions this knowledge pertaining to the decidua has stood me well in hand and led me to the correct diagnosis. In one patient, whose history and physical examination gave no suggestion of ectopic pregnancy, a piece of tissue was seen emerging from the cervix which on examination proved to be pure decidua and contained no chorionic tissue. This finding induced me to make a hysterosalpingogram, which showed a pregnancy aborting from the tube. On another occasion I was witnessing a curettage for an apparently early abortion. The thorough curettage revealed no chorionic tissue but considerable thick decidua. This, plus some new facts garnered from the history, led to an exploratory laparotomy, which revealed an unruptured tubal pregnancy. At times when operation for extra-uterine pregnancy is done early the decidua is not cast off until after the operation. This might cause cramping pain in the uterus and bleeding and might also cause consternation in the mind of the nurse when she finds a piece of tissue coming from

the vagina. On the contrary, the absence of decidua might mean nothing since the decidua may separate and pass out before the curettage takes place.

#### NEEDLING OF THE CULDESAC

It is obvious, when fluid is felt in the posterior culdesac, that one wants to know what the nature of the fluid is. This knowledge is necessary not only from the standpoint of diagnosis but also from the standpoint of treatment. One would not want to evacuate an ovarian cyst or a hematoma by means of a posterior colpotomy. Neither would one want to open a pelvic abscess through an abdominal incision if it could be drained easily through the vagina. Therefore needling of the posterior culdesac is often a great aid in diagnosis. This should be done carefully and with a full knowledge of the anatomy involved. Though there are some arguments against this procedure, in "safe hands" it offers a maximum of diagnostic advantage with a minimum of harm. On many occasions the finding of blood in the posterior culdesac has served me beautifully. But the method has its pitfalls, as witnessed by the case in which I needled the posterior culdesac and obtained the clear fluid of an ovarian cyst. On opening the abdomen in this case, I was much dismayed to find bilateral tubo-ovarian abscesses superimposed on an ovarian cyst lying deep in the pelvis. In another case the needling and finding of blood was not conclusive. This patient denied absolutely the possibility of pregnancy and had no symptoms of ectopic pregnancy. However, she did have a large fluctuant mass in the pelvis which was firmly adherent and which caused considerable pain on one side. The uterus could not be differentiated from the mass. A needling in the fluctuating area behind the uterus revealed dark blood. Notwithstanding this sign, I could not reach the conclusion that this was an ectopic pregnancy. The mass proved to be what I had not thought of—a severe endometriosis with a large chocolate cyst of the ovary. In taking the history I attempted to identify the pain

Fig. 3.—Tubal pregnancy aborting from distal end of right tube. Note how oil seems to drape itself over the aborting pregnancy.

as that associated with endometriosis and, since I could not, I abandoned this possible diagnosis. This case also goes to prove that needling is not conclusive. I do not wish to give the impression that this procedure is harmless and that it is done promiscuously. I do it only when the presence of fluid in the pelvis is obvious. When indicated and when done by "good hands," with a full knowledge of the anatomy involved, it is often an important diagnostic procedure.

As to the diagnostic errors, seven patients were operated on presumably for an ectopic pregnancy. Pyosalpinx was present in four, chocolate cyst in two and a fibroid uterus with intra-uterine pregnancy in one case. As surgery was indicated, no harm was done to the patients.

More serious, diagnostic errors were those made in cases in which the symptoms caused by the ectopic pregnancy were not correctly interpreted. This happened in fifteen cases, or 9 per cent of our 153 cases. Fortunately, the assumed pathologic condition indicated operation, so that the patients were not handicapped by an improper delay.

#### CONCLUSIONS

1. In 153 cases of ectopic pregnancy there was a mortality of two, or 1.96 per cent; there were three deaths, none due directly to operation or to its immediate performance.

2. Prompt diagnosis is of great importance.

3. Careful previous history, intelligent evaluation of uterine bleeding, repeated bimanual examination and the relation between temperature and pulse rate are essential to the elimination of most diagnostic errors.

4. Incorrect interpretation of laboratory observations is the chief source of diagnostic errors in hospitals.

405 Sixth Avenue—15 East Monroe Street.

#### ABSTRACT OF DISCUSSION

DR. THEODORE H. ASCHMANN, Kansas City, Mo.: The results of the authors are gratifying. The mortality rate of ectopic pregnancy is rather high. The doctors' mortality rate reported here was very low. It is known that ectopic pregnancies occur more often than is recognized. Fortunately they do not occur as frequently in the rural districts. One reason is that there is less pelvic inflammation in the rural districts. About 33 per cent of the cases reported by the authors followed pelvic inflammation. About 50 per cent of the patients had previous normal pregnancies. The bleeding is the high point in the paper presented. Continuous red bleeding and the dark brown flow two or three days after the onset of the pain signify that the case is one of extra-uterine pregnancy. One additional diagnostic point that I might add is frequent urination or frequent attempts to urinate followed by a little bleeding.

DR. WALTER T. DANNREUTHER, New York: Except for acute appendicitis, ectopic pregnancy supplies more emergent and tragic cases than any other lesion of the lower abdomen. Few cases conform with the typical textbook description, and correct diagnosis is not always easy. Tubal gestation is most often confused with uterine abortion, salpingitis and spontaneous rupture of an ovarian cyst with intraperitoneal bleeding. The authors are to be commended for their frankness in admitting an erroneous preoperative diagnosis in 9 per cent of 153 cases, and the difficulties they experienced in avoiding additional mistakes. Comparatively, their incidence of error is not high, as Falk in reporting a series of 304 cases recently confessed to an inaccurate diagnosis in 20 per cent. However, it is better to operate on five patients and find that the diagnosis is wrong in four of them than to jeopardize a single one by undue procrastination. The authors made no attempt to review the symptomatology and objective evidence of ectopic pregnancy in their entirety and have not referred to exacerbations of pain with interval soreness in the lower part of the abdomen, the frequent paroxysmal character of the pain, the characteristic discomfort excited by manual traction on the cervix, and the rapidly developing anemia and progressive decline in blood pressure hour by hour which parallel the blood leakage from the tube, all of which are of great significance. The application of the Aschheim-Zondek test is practical and reliable only in the minority of cases in which the gestation sac in the tube is intact. There is a material difference in the clinical picture when the sac is unruptured, after a tubal abortion has begun, and following a sudden perforation of the isthmus portion of the tube with a tear in the mesosalpinx. Usually the severity of the patient's collapse is directly related to the site of implan-

tation; the nearer the sac is to the uterine cornu, the more serious is the effect of rupture. The statement that there was no previous menstrual disturbance in 53 per cent of the patients is surprising. Only 15 per cent of Falk's patients failed to admit a previous amenorrhea. I have found that a delay in the onset of bleeding, an amenorrhea of even one day, is an extremely reliable subjective manifestation in the majority of cases. If every patient suspected of harboring an ectopic pregnancy is hospitalized, a critical history is taken promptly and the available subjective, objective and laboratory data are correlated by an experienced clinician, the incidence of error will be reduced to a minimum.

DR. ERWIN VON GRAFF, Des Moines, Iowa: Dr. Aschmann has mentioned the symptom of frequent urination. We never paid much attention to it. The closest guess would be that the frequent urination is caused by the peritoneal irritation. I am pleased that Dr. Aschmann agrees with the diagnostic importance of the brown discoloration of the discharge. Dr. Dannreuther has criticized us because we did not sufficiently emphasize the symptom of pain and the fact that the bleeding occasionally may be delayed only a few days past the menstrual term. We omitted these points purposely to reduce the size of the paper. It is understood that if there is any delay in the monthly bleeding at all and strictly localized pain, it should not be difficult to make a correct diagnosis. As to the white count, we agree that the higher white count is more in favor of pelvic inflammatory disease and a minor degree of leukocytosis is in favor of ectopic pregnancy. This is quite true. We wanted to emphasize that the presence of leukocytosis should not be indiscriminately used as an argument against the possibility of ectopic pregnancy and in favor of some pelvic inflammation. I am grateful to Dr. Dannreuther that he has emphasized again, as one of the more important points in the diagnosis of ectopic pregnancy, that we should always be suspicious in every case of irregular bleeding in a woman during the child-bearing age; in other words, that the more ectopic minded we are in examining patients with bleeding, the fewer mistakes we make.

#### CANCER OF THE LIP

##### RESULTS OF THERAPY IN FOUR HUNDRED AND TWENTY-FIVE CASES FOLLOWED FROM ONE TO TEN YEARS

UDO J. WILE, M.D.

AND

EUGENE A. HAND, M.D.

Professor of Dermatology and Syphilology; Instructor in Dermatology and Syphilology, respectively, University of Michigan Medical School

ANN ARBOR, MICH.

Over the ten year period that ended Jan. 1, 1935, 425 cases of carcinoma of the lip were seen at the University Clinic. As far as possible by frequent check-up examinations, by contact with the home physicians, and by answers to questionnaires sent to the patients or their families, an attempt has been made to follow to the present time the cases treated.

There has long been an irreconcilable difference of opinion between most dermatologists, surgeons and radiologists regarding the most efficacious method of treatment to be used in this condition. From this group of cases observed over a ten year period and treated by local destruction, surgery and radiation therapy furnish a material from which one may take stock, as it were, of the results achieved to determine a fair and unbiased plan of treatment to be followed in the future in carcinoma of the lip.

Studies and contributions from the Department of Dermatology and Syphilology, University of Michigan Medical School, service of Dr. E. J. Wile.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the reprints.

Read before the Section on Dermatology and Syphilology at the Fifty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

in such a way that it literally drapes itself about the mass and allows the oil-covered mass to be visualized by the x-rays.

In my cases of tubal pregnancy in the midportion of the tube the injected oil went down to the site of the pregnancy and, because this site was apparently well sealed off, ended abruptly and showed in a characteristic shadow. This also proved quite conclusively what has long been suspected by many—that the bleeding from the uterus in cases of tubal pregnancy is from the uterine wall and not from the site of the tubal rupture. While I do not advise hysterosalpingography except when it appears necessary to establish the diagnosis, I do feel that the injection of iodized oil into the uterus and tubes in a case of tubal pregnancy is practically harmless. When the injection is done carefully and by one experienced in its use, there is no reason to believe that it can do harm. I can present sufficient proof that its use is of the highest value. The least that one could say in behalf of hysterosalpingography is that, in case both tubes fill well and normally to their distal ends, one can surely rule out tubal pregnancy.

#### DIFFERENTIAL DIAGNOSIS

Acute appendicitis, salpingitis and twisted ovarian cyst probably are the conditions to be differentiated most frequently from tubal pregnancy. One less common than these, but extremely more difficult of differential diagnosis, is rupture of a graafian follicle or a corpus luteum with sufficient hemorrhage to cause symptoms. This rather rare condition so closely simulates ectopic pregnancy that it defies one to differentiate between them. It has been said that there is no absolute differentiating point. Nevertheless, the hysterosalpingogram should absolutely differentiate between the two.

#### OPERATION

If a reasonable suspicion of ectopic pregnancy exists after careful attempts have been made at diagnosis, the woman should be operated on at once. Blood transfusions should be used freely, if necessary, before, during and after the operation. Only enough blood should be removed from the abdominal cavity to allow a good visualization of the tubes. The fundus of the uterus should be grasped with a fine-pointed volsellum and held up to improve the view. Both tubes and ovaries should be examined carefully, as it is possible that there might be a pregnancy in both tubes. Each ovary should be examined, as the bleeding might be due to an ovarian hemorrhage. The bleeding should be stopped with clamps as soon as it is located. The abdomen should be closed as soon as the operation is over to allow the free blood to remain in it. The appendix should not be removed at operation for tubal pregnancy, as this procedure increases the mortality rate for the operation. When operating for acute appendicitis, if the pathologic changes do not seem to coincide with the diagnosis, the surgeon should carefully sponge deep into the pelvis with a moist sponge stick. By this maneuver he might discover blood in the pelvis which would lead to examination of the tubes and the discovery of a previously unsuspected ectopic pregnancy or hemorrhage from a ruptured follicle or corpus luteum which would have been missed otherwise.

Tubal pregnancy is often very difficult to diagnose. Frequently several, and occasionally all, diagnostic maneuvers at one's disposal must be used before the diagnosis is made.

## THE PREVENTION OF FROST-BITE

LEOPOLD BRAHDY, M.D.

NEW YORK

Because mild, transient frost-bite in American cities is common, one is prone to forget that it may be a serious disease among outdoor workers. In the three winters 1933-1936, this disease caused one death each year among employees of the city of New York. Two of these fatal cases were complicated by diabetes and

one by advanced arteriosclerosis which, in combination with frost-bite, produced fatal gangrene. Other cases, with or without underlying disease, resulted in permanently crippled hands and feet in spite of all treatment (figs. 1-5).

In 1934 a study was made of the conditions under which frost-bite occurs among the city employees exposed to winter weather in the

Fig. 1 (J. T.).—March 1934, loss of index finger.

course of their work.<sup>1</sup> During the past two years 505 new cases have occurred. Experience with these cases has confirmed the opinion previously expressed that the most important factor besides cold is the wind velocity and that the humidity of the atmosphere does not have any effect. However, if the mittens or the socks get wet there is a decidedly increased chance of frost-bite occurring.

In New York City the tall buildings and the ravine-like streets increase the velocity of the wind in some areas. The absence of respiratory infections or other diseases from exposure to the cold was again observed in the last two years. This may not apply in other climates or in cases in which there is prolonged exposure or exhaustion or no physical activity. The present studies are confined to men working in city streets who return to their homes after eight hours of work.

#### TREATMENT

The hope that newer methods of physical therapy would minimize functional loss and the necessity for amputations has not been realized. I have seen excellent results in the treatment of various forms of vascular disease obtained by different technics of physical therapy. No such good results have been obtained in the treatment of frost-bite, although it is usually considered essentially a peripheral vascular lesion. There are physicians who believe in the efficacy of physical therapy in this condition, but examination of their cases often shows that they obtained their good

## THE CASES

The 425 cases were divided into three groups by personal examination or by the description in the record. This division did not take into consideration the question of metastases, which was considered separately. As would be expected, clinical metastases were suspected much more frequently in the moderately advanced and far advanced cases than in the early ones.

The early group includes all those from the smallest to those the size of a nickel (21 mm.). In this were included a few keratoses with suggestive dyskeratotic changes in the epithelium. This group consisted of 216 cases, of which 195 received treatment.

The moderately advanced group includes those from the size of a nickel almost to that of a half dollar (30

The 386 cases treated here were divided into 286 previously untreated cases and 100 cases which are referred to as recurrent cases in which either some form of local treatment or radiation therapy had been given before the patients came to this hospital.

The 286 previously untreated cases were treated at this hospital in the following way:

Thirty cases by surgical excision.

Twenty cases by surgical excision plus roentgen or radium therapy.

Twenty-five cases by surgical excision plus dissection of the cervical lymph glands.

Twenty-nine cases by surgical excision plus dissection of the cervical lymph glands plus roentgen or radium therapy.

Forty-six cases by roentgen or radium therapy.

Eighty-three cases by local destruction.

\* Postoperative.

mm.) in which the lesion was not fixed to the underlying structures of the lip or jaw. This group includes 150 cases, of which 138 received treatment.

All the rest were included in the far advanced group, of which fifty-nine cases were seen and fifty-three received treatment. In many of these cases the treatment was only of a palliative nature, as they seemed inoperable and unsuitable for any form of treatment.

## NO TREATMENT AT THIS HOSPITAL

Thirty-nine patients for one reason or another were discharged without receiving treatment of any kind. This group included twenty-one early, twelve moderately advanced and six far advanced cases. Most of the six far advanced cases were considered hopeless and the patients were discharged home for local care in the form of opiates. Though no attempt has been made to trace any of these thirty-nine patients, it is definitely known that two with far advanced cases of carcinoma died within a short time after discharge, and from their condition at the time of discharge, there is little doubt regarding the fate of the other four far advanced cases.

Fifty-three cases by local destruction plus roentgen or radium therapy.

The group included under apparent cures include all those patients who did not die of cancer of the lip, excluding those in which the cancer recurred to be cured by some other form of therapy than the initial type employed.

The five year cures include all cases in which the patient was alive five years after the initial therapy was given, excluding those cases in which there was recurrence, to be subsequently cured by a different form of therapy.

## SURGICAL EXCISION PLUS OR MINUS ACTINIC OR RADIATION THERAPY

Thirty-four of the fifty-one previously untreated cases treated by surgical excision with or without radiation therapy have been satisfactorily followed. These include fifteen early, fifteen moderately advanced and four far advanced cases; 86.6 per cent of the early, 93.3 per cent of the moderately advanced and 100 per

slight increase from ninety-three to ninety-seven. Although the low incidence among regular employees was not quite maintained in the last year, the change clearly shows the effectiveness of this simple measure. Late in 1935 most (about 80 per cent) temporary snow laborers were given caps with ear laps by the Emergency Relief Bureau. From the 1933-1935 average of

Fig. 7.—Decrease in number of frost-bite cases of hands, feet and ears on snow removal work in the three winters 1933-1936.

ninety-five cases there was a sudden drop to forty-eight cases in the last year.

**Extremities.**—Frost-bite of the ears may cause loss of a few days from work but seldom leaves any permanent effect. Prevention, to be considered effective, must reduce the crippling frost-bite of hands and feet.

Fig. 8.—Temporary laborers in 1935-1936 with work clothing given by the Emergency Relief Bureau.

In 1934 instructions were given to the regular employees on what constituted adequate protection for the hands and feet. The advantages of mittens over gloves and the importance of well fitting shoes and woolen socks were emphasized. That winter the number of frost-bitten extremities among regular employees fell to 47 per cent of the number in 1933-1934 at the

same time that frost-bitten extremities among temporary laborers who received no instructions rose to 177 per cent of the 1933-1934 number. As with frost-bitten ears, the low number of cases of frost-bitten hands and feet was not maintained in the last winter (the most severe of the three). However, among temporary laborers there was a sharp decrease this year, which can be ascribed only to the fact that 80 per cent of these men, in addition to caps, had been given suits, socks, goloshes and mittens. The mittens were felt-lined and wool padded with canvas coverings. The cases dropped from an average of 201 during the two previous winters to fifty-five for 1935-1936. Most significant of all is the fact that among temporary employees suffering frost-bites 50 per cent had not received the equipment. Only 20 per cent of the temporary laborers on the job had not been equipped, and there is an incidence of frost-bite among these men four times as high as among the men who have been equipped with adequate clothing.

## THE DIAGNOSIS OF ECTOPIC PREGNANCY

ERWIN VON GRAFF, M.D.

DES MOINES, IOWA

AND

PRESTON T. BROWN, M.D.

PHOENIX, ARIZ.

Ectopic pregnancy is far from uncommon. According to Schumann,<sup>1</sup> it occurs once in every 300 pregnancies. As the Census Bureau records births but not miscarriages in the United States, it is possible only to estimate the actual number of ectopic pregnancies, but it is safe to say that more than 10,000 occur annually in this country.

There is an appalling mortality of from 5 to 10 per cent or more, and its reduction is largely dependent on sound early diagnosis. Unfortunately, of all gynecologic conditions, there is none involving so many diagnostic errors. Even in well equipped and efficiently supervised institutions, as many as 30 per cent of all ectopic pregnancies are surprises, discovered only during operation.

If this occurs in hospitals with every opportunity for close observation, even a greater number of cases must remain unrecognized in general practice. This may explain the fact that many busy practitioners claim that they seldom see an ectopic pregnancy.

In hospitals, the ectopic pregnancy is usually mistaken for acute appendicitis, pelvic inflammation or ovarian or uterine tumors. The general practitioner is likely to diagnose cases of prolonged bleeding as incomplete intra-uterine abortions. Runge<sup>2</sup> found that, among 234 cases of ectopic pregnancy admitted, forty-five had been mistaken for miscarriage and curettage had been done, with its detrimental influence on the prognosis.

It seems certain that if the mortality in ectopic pregnancy is to be reduced, physicians must learn to recognize it early. If the classic picture of local and general symptoms as depicted in the textbooks and lectures is

far advanced metastases with fixation. The enlarged lymph nodes may be due to metastatic cancer or more often to chronic lymphadenitis from secondary infection of the local lesion.

A clinical diagnosis of enlarged lymph nodes was made in 128 of the cases treated here. A microscopic diagnosis of metastatic carcinoma in the lymph nodes removed, or the appearance of immediate metastases in those in which only the local lesion was treated, occurred in but twenty-five, or 17.5 per cent. Even though but 17 per cent of our cases with glandular enlargement proved to be carcinoma by microscope, nevertheless we concur with those who believe that palpable lymph nodes in cancer of the lip should be dissected in all operable cases.

Of those treated at this hospital, 283 patients had no enlarged glands clinically at the time the diagnosis of cancer of the lip was made here. In the great majority of cases no resection of the suprahyoid nodes was done.

#### LOCAL DESTRUCTION PLUS OR MINUS RADIATION THERAPY

Of the 135 previously untreated cases, 119 treated by local destruction with or without irradiation have been adequately followed.

These cases include ninety-one early and twenty-eight moderately advanced cases; 63.7 per cent of the early and 75 per cent of the moderately advanced cases were proved cancer by pathologic study.

Four, or 4.3 per cent, of the ninety-one early cases recurred with or without metastases and succumbed to cancer of the lip in spite of subsequent therapy of various types. Four others recurred immediately, to respond successfully in two cases to x-rays and in two to local destruction. Two other cases recurred after a number of years to be still active after five and seven years. An apparent cure of eighty-three, or 91.2 per cent, of which forty-nine, or 53.8 per cent, were five year cures, was obtained in these ninety-one early cases.

	Far advanced	3	3	100	3	100	..	....	..	....	1	33.3	..	....	..	....

These cases, however, in which the nodes were not resected were adequately followed for at least a year, during which time clinical metastases did not appear in any case. Four of the few cases in which the suprahyoid nodes were resected showed microscopic metastases. Three of these presented moderately advanced local lesions and the fourth was a recurrent case which was microscopically Broders' type 4.

In cancer of the lip with nonpalpable lymph nodes, therefore, metastases apparently had not occurred in early cases and were seen but rarely in the moderately advanced cases in our series.

Though we strongly advocate frequent check-up examinations in the first year following treatment to the local lesion in order to diagnose early that rare case in which metastases appear following the local treatment, we do not advocate subjecting these patients to the pain, expense, loss of time and danger of surgical dissection of the lymph nodes.

It is our opinion from comparing groups with and without roentgen therapy to the regional nodes that high voltage roentgen therapy to the glands is useless as a prophylaxis against metastasis, and for that reason we do not advocate its use for this purpose.

One of the twenty-eight moderately advanced cases recurred and death was due to cancer of the lip. An immediate metastasis occurred in one other case, which was treated by dissection of the metastatic nodes, to result in a nine year cure. An immediate recurrence took place in three cases; surgical excision in one resulted in a ten year cure, surgical excision plus dissection of the uninvolved suprahyoid lymph nodes resulted in a two year cure, and local destruction plus roentgen therapy resulted in a four year cure in the third. An apparent cure of twenty-four, or 91.4 per cent, and a five year cure of fourteen, or 50 per cent, were obtained in these twenty-eight moderately advanced cases.

Owing in part to the fact that many of the apparent cures have not been followed long enough to be five year cures, the results with local destruction, while excellent here, are not quite as good as those of Stevens,<sup>13</sup> with 80 per cent five year cures, Pfahler and Vastine,<sup>14</sup> with 96 per cent five year cures, and the

13. Stevens, J. T.: Electrothermic Surgery in the Management of Carcinoma of the Lip, *Am. J. Surg.* 7: 831-835 (Dec.) 1927.

brown color. This characteristic was definitely recorded thirty times, and its frequency increased after its significance was appreciated. The brown discharge is almost pathognomonic. We recall only a single case in which this symptom misled us and the operation revealed a chocolate cyst.

As important as the color is the duration of bleeding. In intra-uterine abortion, since the pregnancy is not far advanced, the flow usually stops with the spontaneous completion of the miscarriage. Bed rest affects it favorably and oxytocics are efficient. In tubal abortion, the discharge goes on regardless of treatment.

On the whole, strict observation of the character of the bleeding is essential to correct diagnosis.

In connection with local symptoms and physical examination, the obvious is again omitted, but the fact must be emphasized that a tubal abortion may exist without pain, moderate but intractable bleeding being the only sign, as was the case shown in figure 1, which was correctly diagnosed before operation by this single symptom. Anemia is very often not marked. Unilateral mydriasis,<sup>5</sup> pain in the shoulder, and discoloration of the navel, known as Cullen's<sup>6</sup> sign, are helpful if present but are extremely rare. In the bimanual examination, the finding of an adnexal mass on one side is highly indicative. The absence or presence of tenderness is of no consequence. If, in addition, there is a

TABLE 3.—*Differentiation Between Extra-Uterine and Intra-Uterine Abortion*

doughy resistance in the Douglas pouch, the diagnosis is definitely positive. It should be kept in mind that the hematocele is frequently located in front of the uterine body and tightly attached to it, giving the same impression as a uterine fibroid, for which it is often mistaken. In cases in which the abdominal ostium of the tube is closed there may be no hematocele. This is easily confused with a pus tube (fig. 2).

Another point that should be mentioned is that the mechanical irritation of a bimanual examination is often followed by a conspicuous enlargement or other change in the condition within twenty-four to forty-eight hours. As a rule, this rapid growth due to further bleeding does not produce the pain and fever that are inevitable after manipulation of pus tubes or other inflamed pelvic organs.

Needling of the culdesac is a generally accepted and extremely helpful diagnostic procedure. Because of the danger of infection, it should be performed only as a preliminary to laparotomy.

A scrupulously accurate history, intelligent evaluation of the bleeding, and competent, repeated bimanual examinations should usually make possible the diagnosis of ectopic pregnancy. At least the differentiation between intra-uterine and extra-uterine abortion should be clear. This would eliminate the commonest diagnostic error encountered in general practice.

Not so in the hospital. Here one sees the condition mistaken for appendicitis, pelvic inflammation, fibroids and ovarian tumors. Many years of clinical work have convinced us that this is due to certain established prejudices in the interpretation of laboratory observations, illustrated by table 4.

The hemoglobin and red blood cell count often do not suggest intra-abdominal bleeding.

The white cells are frequently increased to such an extent as to suggest infection. This explains the fre-

quent erroneous diagnosis of acute pelvic inflammation or appendicitis. The highest number of white cells, 24,000, was found in a case of rupture, the abdomen containing a considerable amount of blood. The lowest white cell count of 4,800 was present in a case of infected tubal abortion showing a pus tube containing hemolytic streptococci. There was a generalized peritonitis, so that a hysterectomy had to be performed in order to secure proper drainage.

The urobilinogen test, known as a highly sensitive reaction in the presence of extravascular blood, caused us to suspect ectopic pregnancy in three cases of pyosalpinx.

A positive biologic pregnancy reaction is very helpful, but a negative finding is not conclusive. Treatment therefore should never be delayed for the sole purpose of making a pregnancy test.

On the whole, table 4 shows how easily the laboratory examinations may be misleading. Every effort should be made to form an opinion from the history, obser-

TABLE 5.—*Febrile and Afebrile Cases*

vations and examination, which are accessible to every physician regardless of his equipment.

Of greater importance than commonly acknowledged is the relationship between temperature and pulse rate. The temperature was normal and elevated in equal proportions. Only two patients had fever over 101 F. Nine cases of each group are recorded in table 5.

In either febrile or nonfebrile cases the pulse rate is unusually high. This is not surprising with marked anemia and shock but may be present even when the patient's general condition is good. It is apparently due to the peritoneal irritation by the blood and should be given due attention.

few of these cases, roentgen therapy locally or to the glands was combined with surgery or local destruction.

Of this group, forty-nine cases were adequately followed. Table 4 would seem to indicate that the results in this group, though not as satisfactory as in the fresh cases, were still excellent. This was particularly true of the cases that were treated by local destruction. The percentage of moderately advanced and far advanced cases was larger in this group, as would be expected, than in the previously untreated group.

In cases treated by surgical excision plus block dissection of the regional nodes, 33⅓ per cent showed definite microscopic metastases. Death from carcinoma occurred in a short time in all the cases that were followed. This very poor result in these recurrent cases with metastatic glands is compared to the 62.5 per cent five year cures in those previously untreated cases presenting positive lymph nodes.

Of the thirty-five who received inadequate radium or roentgen therapy prior to receiving therapy here, the treatment here consisted of local destruction in fourteen, irradiation in six, surgical excision in five and surgical excision plus dissection of the regional nodes in ten.

From the thirty-one cases of this group that have been adequately followed, the final results as indicated

treatment and forecasting prognosis, there has been a difference of opinion regarding the reliability of his criteria.

From the study of 108 cases of carcinoma of the lip treated by surgical excision with or without gland resection in which adequate microscopic slides were available, an attempt has been made to determine the relation between cell type, prognosis and early metastasis.

Brewer<sup>8</sup> and others have noted that basal cell carcinoma of the mucous membrane of the lip is an extremely rare condition. On the other hand, Muir<sup>11</sup> stated that basal cell lesions were often seen. Certainly numerous cases begin as basal cell carcinomas of the skin of the lip and invade the mucous membrane secondarily. In almost every case in which this involvement of the mucous membrane takes place, the carcinoma cell type changes to squamous cell type. Only rarely does the lesion remain basal cell in type on the mucous membrane. In only three of the 425 cases was a diagnosis of basal cell carcinoma made from the microscopic slide. Two of these cases were included in the 108 cases reported as treated by surgical excision.

The prognosis in basal cell carcinoma of the lip is extremely good. Metastases are almost unknown. The three patients with basal cell carcinoma in our series are alive and well over nine years.

TABLE 5.—Carcinomas According to Cell Type

	Number	Per Cent	Dead		Dead of Cancer		Recurrent		Metastatic		Relative Cures		Five Year Cures	
			Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent
Type 1	38	34.1	9	23.6	2	5.2	1	2.6	1	2.6	34	92.1	20	52.1
Type 2	38	34.1	15	39.7	5	13.2	..	....	1	2.6	32	86.9	15	39.7
Type 3	21	19.8	11	52.3	8	38	..	....	1	4.7	12	57.1	8	38
Type 4	9	8.4	8	88.8	8	88.8	1	11.1	..	....	0	....	0	....

in table 4 show that the results were poor. The percentage of five year and apparent cures was lower in almost every form of treatment than in a corresponding group of previously untreated cases or recurrent secondary cases that had received local traumatic therapy outside the hospital.

The results in those which received roentgen or radium therapy alone were particularly poor, since death occurred in five out of six that were followed, in four of which it was due definitely to carcinoma. These cases were moderately advanced or far advanced cases and apparently were radioresistant to x-rays or radium from previous radiation therapy.

The 100 per cent failure in those cases in this series presenting microscopic metastases on resection of the enlarged lymph nodes is parallel to the 100 per cent failure in that group in our series in which local surgical therapy was given prior to excision of the local lesion and dissection of the lymph nodes.

Grouping the previously untreated and recurrent cases here, we find a 35.7 per cent five year cure in cases presenting positive lymph nodes on dissection of the regional lymph nodes. Attention is drawn again to the fact that all the five year cures occurred in the previously untreated group, and in all these five year cures the metastases were microscopic at the time of operation.

#### MICROSCOPIC PATHOLOGIC CHANGES OF THE PRIMARY LESION AND THEIR CORRELATION TO PROGNOSIS AND METASTASIS

Since the introduction by Broders of the division of carcinomas into groups according to cell type to aid in

From table 5 it will be seen that these 106 cases consisted of thirty-eight, or 34.1 per cent, type 1, thirty-eight, or 34.1 per cent, type 2, twenty-one, or 19.8 per cent, type 3, and nine, or 8.4 per cent, type 4.

Nine, or 23.6 per cent, of the thirty-eight type 1 cases were fatal, two deaths of which were due to carcinoma of the lip. One case was metastatic and one was recurrent. The two deaths from cancer of the lip and the metastatic case were recurrent cases and far advanced at the time of diagnosis and treatment here. A relative cure of 92.1 per cent, of which twenty, or 52.6 per cent, were five year cures, was obtained in this group.

The results in types 2 and 3 in table 5 were progressively worse.

Of the nine type 4 cases, death due to cancer of the lip occurred in eight, and the final case was recurrent with local extension to the mandible. Since in this series recovery has not occurred in any case in which the bone was invaded, the ultimate result in the last case can easily be forecast.

The cell type in cancer of the lip is apparently of prognostic value and should be used for this purpose and also may serve as a guide to the best mode of treatment.

#### SUMMARY AND CONCLUSIONS

1. Smoking is apparently of some importance in the background of cancer of the lip.

2. Precancerous lesions of the lip such as keratoses, leukoplakia, chronic ulcers, cutaneous horns, and fib-

18. Muir, J.: Cancer of the Lower Lip: Suggestions as to Its Prevention and Treatment by Radiation. *Internat. J. Med. & Surg.* 46:522-524 (Dec.) 1933.

A study of those other factors which affect the ultimate prognosis such as age, sex, color, location of the lesions, approximate time interval between onset and treatment, previous treatment, stage of the carcinoma, presence or absence of clinical and microscopic metastases, type of carcinoma and microscopic cell type has been made, and these factors will be correlated when possible in this paper.

#### CLINICAL TYPES

Most cases of carcinoma of the lip fall into two clinical types: the papillary superficial elevated type and the ulcerative infiltrative type.

The papillary type, which was the more frequent in this series, is the type that usually begins from a keratosis or a leukoplakic lesion. This type usually remains locally malignant for a considerable period of time, then extends slowly, and ulcerates late in its course. With the advent of ulceration, metastasis to the regional nodes may occur. This type is ordinarily included in Broders' type 1 or type 2 from the microscopic study of the cells. It carries a much better prognosis than the ulcerative infiltrative type.

The ulcerative infiltrative type commonly begins from a fissure, a secondarily infected cut, a minor injury or a chronic ulcer. These lesions ulcerate, break down early and have an early tendency to metastasize. The prognosis is much worse than the papillary type. The cell type customarily is that of Broders' type 3 or 4.

#### SEX

Of these cases 410, or 96.4 per cent, occurred in males and fifteen, or 3.6 per cent, in females. This marked difference in frequency in the sexes has been noted by most others. Elliott<sup>1</sup> found 87.9 per cent in males, Kelly<sup>2</sup> 93.25 per cent, and Hyndman<sup>3</sup> 97.3 per cent. Some of the factors that may account for part of this difference will be discussed under smoking.

Of the fifteen female patients, five received no treatment here, seven received local destruction with or without radiation therapy, and three received roentgen therapy.

Of the seven cases that received local destruction, five were early, one moderately advanced and one far advanced. Omitting the one far advanced case presenting metastasis in which death from carcinoma occurred, the remaining six cases, as was expected, were cured from two to nine years following local destruction.

The three cases in which roentgen therapy was given consisted of two early cases and one far advanced case. In the far advanced case there has been no recurrence or metastasis and the patient is still alive. Both of the early cases were cured and in one case for more than five years.

Though this group of fifteen is a somewhat small number from which to draw conclusions, the ultimate prognosis in lip cancer seems to be better in the female than in the male in our series.

#### LOCATION

Of the lesions in both sexes, 93.3 per cent appeared on the lower lip, 4.7 per cent on the upper and 2 per cent at the angles.

#### AGE

The average age incidence for the entire series was 65.2 years. The average age of the fifteen women was 61.09, which was lower than that of the men, the latter being 65.4 years. The youngest woman affected was 45, the oldest 91.

From table 1, a study of the final results in those cases followed according to age, it may be seen that the younger groups fared much better than older groups. The percentage of deaths increased rapidly with age, as would be expected in any such group of individuals with or without disease. On the other hand, the percentage of deaths from carcinoma increased progressively also, though not quite as rapidly as the total deaths. Vice versa, the percentage of relative and five year cures decreased as the age increased. These results are very interesting in that it is generally believed that most cancers appearing in young persons are more malignant and carry a proportionately poorer prognosis.

#### SYPHILIS

A definite history of syphilis or a positive serologic reaction occurred in 4 per cent of the group, which is about the same proportion found in the general admission to this hospital. It is interesting to compare this infrequent association of syphilis and cancer of the lip with the frequent association of syphilis and cancer of the tongue. Eller and Anderson<sup>4</sup> state their belief that cancer and tertiary syphilis of the tongue are associated in 60 per cent of the cases. In a report from this clinic, Belote<sup>5</sup> found almost 30 per cent of the carcinomas of the tongue to present positive serologic reactions.

Syphilis apparently was of no great importance as an etiologic factor in our series, an interesting contrast to cancer of the tongue studied from the same material.

#### SMOKING

Of the patients, 138, or 32 per cent, gave a definite history of moderate to excessive use of tobacco, and in many of these cases habitual pipe smoking was noted in the history. The percentage of tobacco users was undoubtedly much higher, as many of the records were incomplete regarding this matter.

Certainly in many of these cases smoking seemed to have been of importance in the etiology of cancer of the lip. In a number of cases the cancer definitely appeared on the site of the smoker's patch or leukoplakia where the pipe had rested for years. On the other hand, in 15 per cent of the cases at least, cancer of the lip appeared in individuals who had never used tobacco in any form.

It is interesting to note Brewer's<sup>6</sup> observation that, in a group of white women over 70 years of age, 8.04 per hundred thousand died of carcinoma of the lip, while in a like number of Negro women in which pipe smoking was very common 30.1 per hundred thousand succumbed to cancer of the lip.

The greater prevalence of smoking, particularly pipe smoking, in the male may account in part for the great preponderance of cases occurring in males.

The presence of leukoplakia on the lip prior to the cancer was noted in a number of the cases. In most of these cases the leukoplakia was associated with the use of tobacco, though in several the presence of a positive serologic reaction was noted.

because it is usually painful. Later it should be done vigorously until the lip reforms and the scar has entirely disappeared with renewal of the vermilion border.

DR. MERLIN T.-R. MAYNARD, San Jose, Calif.: Because radiation therapy is under criticism at the present time, I feel that something should be said in its defense. My feeling is that when one cannot palpate a node in the presence of a lip cancer one should cut down on the adjacent node area and remove one or two nodes for sectioning. Early cancer may be found in these nodes before the palpable stage. I believe that this should be done in every case in which the lesion has been active long enough to metastasize. As to the classification by size, I think that thickness is more important than size; infiltration of the lesion should be considered. A pea size lesion may be heavily infiltrated and very active, whereas a quarter or fifty cent size lesion (from 25 to 30 mm.) may be very scirrhous and very slow to metastasize. I suggest that, in the electrodesiccation of these lesions, after desiccating one always curette away all the desiccated material. It will often be found that one has not gone deep enough and one will desiccate further. Many dermatologists desiccate and do not remove their desiccated material, and do not realize that they haven't gone very deep; they miss some of the lesion. Curettage should always follow desiccation. There have been some great changes in the irradiation of these lesions within the last few years. The methods of Coutard and of Chaoul of Berlin have altered greatly that side of the question. Chaoul, using a short skin distance, one of 5 cm. with a special tube, has had 90.5 per cent cures in lip cancer. Coutard technic and Coutard modifications give 95.4 per cent of cures. Those, of course, are properly selected cases. I wouldn't think of using radiation in cases in which there are deep infiltration and heavily infiltrated nodes as well. When, however, the lesions are thin and relatively early, I believe that the Coutard method or modifications should be practiced.

DR. H. J. TEMPLETON, Oakland, Calif.: I wish to discuss the treatment of the local lesion in cases in which there are no palpable glands. These lesions can be cured by different methods of attack, and every one feels that that method is best with which the individual operator is most familiar. I have a strong feeling, however, that any method of radical destruction, whether it is Dr. Percy's cautery, electrocoagulation or widespread surgical excision, is in general preferable to irradiation, and I base my argument on one point. That point is that the most enthusiastic advocate of irradiation must admit that not all tumor cells are radiosensitive. All have seen the exceptional case that would not yield even to 5,000 roentgens in split or single dosage, whereas it is inconceivable that any cancer cell could resist the actual cautery, widespread electrocoagulation or widespread surgery. I think that this argument, as far as the local lesion is concerned, is almost irrefutable. I have just one point with regard to the destructive technic which is of practical importance. Many of these patients can be taken care of in the office. If one wishes to destroy the lower lip, a dentist can do a double mandibular nerve block. This will give an anesthesia sufficient for almost any degree of destruction.

DR. HARRY P. JACOBSON, Los Angeles: Dr. Percy's reference to the fact that he has many referred cases of cutaneous malignant growths from dermatologic colleagues who have been unsuccessful in their treatment is perfectly true. I want to remind Dr. Percy, however, that I know and he knows that he receives a good many more similar cases from other specialists and especially from our surgical friends. That would seem to make the score even. The gist of the situation is this: The treatment of lip cancer is a serious undertaking, requiring agents possessed of destructive qualities and operators able, willing and unafraid to employ these agents skilfully and adequately. I am a disciple of Dr. Percy's; that is, in a dermatologic sense. I have been much impressed with the efficacy of the Percy method in the management of cutaneous malignant growths. In my own work, both in the hospital and in the office, I have in the past few years been handling practically all cutaneous malignant growths (with an occasional exception) by means of the actual cautery, and I am fairly convinced that

for routine purposes nothing compares with it as far as results are concerned. The cautery method is simple of application, seldom requires anesthesia or hospitalization of the patient, is certain to destroy the cancer process when adequately employed, and the final cosmetic results are usually quite acceptable.

DR. EVERETT C. FOX, Dallas, Texas: There has been much discussion this morning about cauterization and other measures of treatment of lip carcinoma. In the clinic where we do not have radiation service available, my associates and I have used much the type of method that the authors have reported, but in private practice better results and certainly far better cosmetic results can be obtained by irradiation alone. We are using roentgen radiation for the smaller cases, two to three erythema doses (680 roentgens) on alternate days for four or five doses, and a perfectly normal lip results. For the larger cases we use the small platinum radium needles, 1 mg. to each running centimeter of needle, and the needle is placed beneath the border of the lesion. The needles are left in from five to seven days, producing approximately 100 milligram hours for each needle. This method has been very successful in our hands, and we prefer radiation therapy for cancer of the lip of any size rather than some of the previous destructive measures that we formerly used.

DR. C. F. LEHMANN, San Antonio, Texas: There is no controversy about the treating of cancer of the lip, provided it is destructive. The purpose of my remarks is to consider the rehabilitation of the patient. There is one part of the treatment of cancer of the lip in which radium, I think, is misused, and that is the application of radium to previously treated cancer in which there is atrophy and scar. It is in that individual that radiation should not be used; it only contributes to more atrophy, it leaves a lip that is vulnerable. Many of these patients are strong men, exposed to the sun and to irritating wind. They have a lip that will not hold up, and in some cases the cautery is an appealing method of treatment. Many times one wishes the patient had had the cautery operation early, primarily because it does leave a soft, supple, pliable, tough scar—either that or surgery. Insufficient surgical methods are responsible for many failures, just as much as the piddling methods used by dermatologists. It has been my experience to see just as many failures from poor surgery as from piddling methods such as trichloroacetic acid or light fulguration.

DR. UDO J. WILE, Ann Arbor, Mich.: Dr. Everett Lain's criticisms were well taken. We have had no real experience with the treatment of cancer of the lip by means of irradiation. That is done in our hospital in the department of roentgenology. But it seemed proper to take their results and to compare them with ours and with those of the surgeon and to draw the conclusion at least that in our hands, that is at the University Hospital, the irradiation methods have not shown as adequate and satisfactory results as the method of destruction. I endorse what Dr. Percy said about heat. Many of our cases have been treated with the actual cautery and I have a great fondness for the galvanocautery for the immediate eradication of such cases as look promising at the outset by this method. I want to call attention to one of the points in our paper which was touched on by Dr. Maynard, and that is the degree of actual involvement of the lymph nodes when they are palpable. I cannot subscribe to the view, nor do I think it is a proper procedure, to remove a lymph node in the complete absence of any suspicion that such a node might be involved. In the total number of palpable lymph nodes only one out of five shows cancer. The majority of them, therefore, are lymphadenitis and not cancer at all. However, the incidence of 20 per cent of actual cancer is certainly a good argument for the removal of all the lymph nodes that can be reached when they are palpable. I cannot subscribe, and I don't think Dr. Hand would either, to the practice of removing a node in the immediate neighborhood or any node for the purpose of ascertaining whether metastasis has taken place where it is not suspected. I endorse Dr. Templeton's remarks. The results with radium in the University Hospital clinic have been decidedly better than those with the x-rays. Dr. Lehmann's remarks were perfectly properly taken. Improper surgery, improper methods of any kind, fall far short of adequate cure. The surgeon is as much responsible for failures as is the dermatologist.

cent of the far advanced were proved carcinoma by pathologic examination.

In two cases, or 13.3 per cent of the fifteen early cases, death was due to cancer of the lip. One recurred after four years, to be still active. An immediate recurrence took place in two cases; one was then treated by surgical excision, to result in a three year cure, and one by local destruction to end in death of unknown etiology. An apparent cure of eleven, or 73.3 per cent, for from one to eleven years, of which five, or 33⅓ per cent, were five year cures, was obtained in this group.

Of the fifteen moderately advanced cases, three patients, or 20 per cent, were dead of cancer of the lip. One case recurred with metastases, to progress in spite of further roentgen therapy. Another recurred immediately, to be treated by local destruction plus roentgen therapy to the glands, resulting in a five year cure. An apparent cure of ten, or 66⅔ per cent for from one to eleven years, of which six, or 40 per cent, were five year cures, was obtained in this group.

Of the far advanced cases, three patients, or 75 per cent, were treated surgically as a palliative measure

One of the early cases presented an immediate recurrence, which was still progressive with metastases in spite of surgical excision. An apparent cure for from one to eleven years in twelve, or 92.5 per cent, of which eight, or 61.5 per cent, were five year cures, was obtained in this group.

Six, or 35.2 per cent, of the seventeen moderately advanced cases were fatal, of which one was post operative. An apparent cure of sixteen, or 94.1 per cent, for from one to eleven years, of which nine, or 52.9 per cent, were five year cures, was obtained in this group.

Two, or 40 per cent, of the five far advanced cases were fatal, one of cancer of the lip and one of intercurrent disease after five years. Two were cured for respectively one and five years, and the final case was recurrent with metastases when last seen.

The excellent results in these cases treated by surgical excision, plus dissection of the suprahyoid lymph nodes, which were negative microscopically, compare favorably with those of Brewer,<sup>8</sup> who reported 92 per cent of five year cures in a similar group.

TABLE 3.—Comparison of Results of Surgical Excision or Local Destruction With and Without Irradiation to Regional Nodes

only and died of carcinoma of the lip. The fourth patient, in whom the cell type was Broders' type 3, which was radiosensitive, received surgical excision plus heavy doses of roentgen therapy and was alive more than five years later. The local lesion was not fixed in this case to the deep structures, nor was there any evidence of metastases clinically.

No cases of postoperative death occurred in this group. From a comparison of those cases treated by surgical excision alone and those in which some form of radiation therapy was given later following the surgical excision, we have come to the conclusion that this subsequent radiation therapy is unnecessary.

#### SURGICAL EXCISION PLUS DISSECTION OF THE REGIONAL LYMPH NODES WITH OR WITHOUT RADIATION THERAPY

Forty-three of the fifty-five previously untreated cases in which surgical excision was done plus dissection of the regional lymph nodes with or without roentgen or radium therapy have been satisfactorily followed. These forty-three cases, which were all proved by microscopic examination, consisted of thirty-five cases in which the removed lymph nodes were negative microscopically and eight cases in which the lymph nodes showed positive metastases.

The thirty-five cases presenting negative nodes consisted of thirteen early, seventeen moderately advanced and five far advanced cases.

The eight cases presenting positive nodes include two early, five moderately advanced and one far advanced.

Three, or 37.5 per cent, of these eight patients succumbed to carcinoma of the lip. Two of these were Broders' type 3 and one was type 4. Five, or 62.5 per cent, were cured for from five to nine years. The metastasis in each of these cured cases was microscopic.

The suprahyoid lymph nodes were resected in a total of ninety-seven cases. The postoperative death rate of one, or 1.03 per cent, was somewhat higher than that reported by others, such as Figi,<sup>6</sup> of 0.42 per cent. The postoperative death occurred in a man aged 65 with a moderately advanced lesion, who was considered to have been a good operative risk. Metastases were not felt to be present clinically in this case, nor were they present on microscopic study.

There is very little difference of opinion regarding the treatment to be used in palpable nodes in cancer of the lip. Eller,<sup>11</sup> MacKee,<sup>11</sup> Collier,<sup>11</sup> Bloodgood<sup>11</sup> and others advocate surgical dissection of palpable glands unless the nodes are fixed or the case is inoperable for other reasons. Most of these workers also advocate postoperative irradiation and in a few cases preoperatively.

It is impossible to make a definite clinical diagnosis of metastatic glands in cancer of the lip except in the
